1 SUMMARY

For military communication purposes a wideband class-AB power amplifier has been designed around the BLF 245 with the frequency range 25 to 110 MHz.

The DC-setting is $V_D = 28$ V and $I_{DQ} = 200$ mA.

In the input and output matching networks asymmetrical 1 : 4 transformers on 4C6 ferrite core material have been applied.

2 INTRODUCTION

The BLF245 is an RF power MOS transistor for the VHF frequency range in a SOT123 encapsulation.

For application in military communication equipment a wideband power amplifier has been developed with a frequency range from 25 to 110 MHz. The transistor operates in class-AB at $V_{DS} = 28$ V and a quiescent current $I_{DQ} = 200$ mA. The useful output power is in the range of $25 – 30$ W.

3 DESIGN OF THE AMPLIFIER

3.1 General remarks

The amplifier has been developed with 1 : 4 impedance transformers in the input as well as in the output circuit. These transformers of the transmission line type with a ferrite core transform the 50 $\Omega$ system impedance at the input and output to about 12.5 $\Omega$. An LC compensation circuit has been applied to transform this 12.5 $\Omega$ to the optimum load impedance of the transistor. At the input a circuit matches the 12.5 $\Omega$ to the gate impedance of the transistor and also takes care of a flat gain over the whole bandwidth.

3.2 Output circuit

For an optimum alignment of the output circuit the transistor has been replaced by a dummy. This dummy consists of a resistor of 12 $\Omega$ parallel with a capacitor of 82 pF. The real part of the dummy has been determined by the available drain voltage and the required output power.

$$R_L = \frac{V_D^2}{2P_O} \rightarrow R_L = \frac{28^2}{2 \times 30} = 13.1 \, \Omega$$

This is near to the value of 12.5 $\Omega$ mentioned in Section 3.1. The capacitor is about 15% higher than the output capacitance of the transistor. The RF choke at the drain side must have a sufficient high reactance at the lower end of the frequency range. Choosing this reactance appr. a factor 5 higher than the transistor loadresistance we get an inductance of 455 nH for $L_4$.

The output capacitance of the transistor can be compensated according to the Appendix. The result is: $L_6 = 18.6$ nH and $C_{11} = 82$ pF. To transform the achieved 12.5 $\Omega$ to the 50 $\Omega$ system impedance an asymmetrical 1 : 4 transformer has
been used. Information about this kind of transformation can be found in Refs 1 and 2. For the transformer a toroid of 4C6 material has been used. Dimensions: $23 \times 14 \times 7$ mm. On this toroid 5 turns of two 0.7 mm twisted enamelled Cu-wires are uniformly distributed and connected as shown in Fig.1.

With the aid of a network analyser the transformer has been corrected for higher frequencies. With $C_l = 68$ pF and $C_h = 12$ pF the return losses in the range $20 - 140$ MHz are better than $-30$ dB (VSWR $< 1.07$). Optimization of the complete output circuit has been carried out by measuring the return losses at the output with the network analyser under swept condition (see Fig.2).
A wideband power amplifier (25 – 110 MHz) with the MOS transistor BLF245

Figure 4 shows the return losses of the output circuit before and after practical optimization. By decreasing $L_6$ to 10 nH and $C_{12}$ to 43 pF the return losses improved about 10 dB in the frequency range 20 to 140 MHz to $-20$ dB ($VSWR = 1.22$).

### 3.3 Input circuit

As mentioned in Section 3.1 a special circuit matches the input impedance of the transistor to 12.5 $\Omega$ and also takes care of a sufficient flat gain over the whole bandwidth. To determine the gate-source impedance and the gain of the transistor in combination with the output circuit described in Section 3.2, narrow band input circuits have been used at several frequencies. By tuning such an auxiliary input circuit the gain of the transistor in combination with the output circuit can be measured directly. In case the input circuit has been tuned the output impedance of this circuit is the conjugate complex of the input impedance of the transistor.

Figs 5 to 7 give the input impedance and the gain of the transistor in combination with the output circuit. The matching network chosen at the input of the transistor is depicted in Fig.3.

![Fig.3 Input matching circuit.](image)

$C_i$ represents the input capacitance of the BLF245 which is appr. 220 pF (see Fig.6). Across this capacitor a constant voltage versus frequency from 25 up to 110 MHz has to be developed. Provided $C_i$ is an ideal capacitance the optimum dimensioning of this network is as follows:

- $R_G = R_1 = 1.6/\omega_c C_i = 10.5 \, \Omega$
- $C_2 = C_5 = 0.386 \, C_i = 85 \, \text{pF}$
- $L_2 = L_3 = 0.997 R_1/\omega_c = 15.1 \, \text{nH}$

in which $\omega_c$ is the maximum angular frequency. The calculated voltage variation across $C_i$ is $\pm 0.36$ dB and the maximum VSWR seen by the generator is 1.36. Deviating from this calculation, for the ease of transformation, $R_G$ and $R_1$ have been chosen 12.5 $\Omega$. Further the resistive component of $C_i$ is substantial especially at higher frequencies.

Therefore the values of the components have been changed in a computer optimization program for a maximally flat gain and a low input VSWR. This optimization results in a gain of 17.5 dB with a variation of $\pm 0.17$ dB and a maximum VSWR = 1.177. These results have been achieved by changing the components of Fig.3:

- $C_2 = 97 \, \text{pF}$, $C_5 = 102 \, \text{pF}$, $L_2 = 17.6 \, \text{nH}$, $L_3 = 29 \, \text{nH}$ and $R_1 = 12 \, \Omega$.

The remaining part of the transformation from 12.5 $\Omega$ to the 50 $\Omega$ system impedance has been accomplished with a transformer similar to the output transformer. However the input transformer has been wound on a core consisting of 2 small toroids of 4C6 material ($6 \times 4 \times 2$ mm).
A wideband power amplifier (25 – 110 MHz) with the MOS transistor BLF245

On this core 6 turns of two 0.25 mm twisted enamelled Cu-wires are uniformly distributed similar to the output transformer described in Section 3.2. (see Fig.1). With correction capacitors at the high ohmic and the low ohmic side of respectively 8.2 and 47 pF the return losses in the range 20 – 140 MHz are better than −27 dB (VSWR ≤ 1.1).

For the practical optimization of the complete inputcircuit the transistor has been adjusted at $V_D = 28 \text{ V}$ and a quiescent current $I_DQ = 200 \text{ mA}$. The gain and input return losses have been measured in the frequency range of 20 up to 110 MHz.

The best results have been achieved by changing the correction capacitor $C_3$ from 47 to 62 pF and by executing $R_1$ as a parallel connection of 5 resistors of 61.9 Ω.

Figure 8 gives the complete circuit diagram of the BLF245 wideband amplifier and Table 3 gives the corresponding parts list.

4 MEASURED PERFORMANCE

4.1 Constant input power

Figs 9 to 11 give the gain, efficiency and output power versus the frequency at a constant input power ($P_i = 0.5 \text{ W}$).

In the frequency range of 25 to 110 MHz the gain is 17.2 to 17.9 dB, the efficiency 55 to 70% and the output power 26.5 to 30.5 W.

4.2 Constant output power

Figs 12 and 13 give the gain and efficiency versus the frequency at a constant power ($P_O = 27.5 \text{ W}$) and heatsink temperatures of 25 and 70 °C.

Figs 14 and 15 give the input return losses and the 2e and 3e harmonics of the output signal also versus the frequency. The return losses have been measured at a heatsink temperature of 25 and 70 °C. The harmonics have been measured at 25 °C. By increasing the heatsink temperature from 25 to 70 °C the gain decreases about 1.2 dB. The heatsink temperature has no influence on efficiency and return losses. At 25 °C the gain of the amplifier varies from 17.2 to 18.2 dB, the efficiency from 55 to 67% and the return losses at the input are at least −14 dB (VSWR ≤ 1.6). Also the 2e and 3e harmonics are at least 14 dB down.

4.3 Constant frequency

Figs 16 to 18 give the output power versus input power and the gain and efficiency versus power at 4 frequencies.

4.4 Stability

Applying an R&S PTU low pass filter at the output of the amplifier stability measurements have been carried out. Choosing a low pass frequency as close as possible above the measuring frequency the amplifier was stable through the whole frequency range of 25 to 110 MHz.

4.5 Mismatch

The amplifier has been tested for load mismatch at all phase angles. Up to VSWR = 10 : 1 the amplifier is stable. At VSWR = 20 : 1 the amplifier is only stable below 70 MHz. However also at higher frequencies degradation of the RF performance did not occur.

5 CONCLUSIONS

Based on the results presented in this report it may be concluded that it is quite possible to design a wideband amplifier from 25 to 110 MHz with a very good performance using the MOS transistor BLF 245.

7 APPENDIX

The output capacitance of a transistor can be compensated over a certain bandwidth by absorbing it in a low-pass Chebyshev π-section.

If \( C_1 \) is the transistor output capacitance the components \( L \) and \( C_2 \) must be added. \( C_2 = C_1 = C \)

The normalized value of \( C \) is: \( A = \omega_m C R \)
In which \( \omega_m = 2 \pi f_{\text{max}} \)

Now we can calculate the normalized value of \( L \) with:
\[ B = \frac{8A}{3A^2 + 4} \]
where \( B = \omega_m L/R \)

The maximum VSWR of this network can be calculated with the following procedure.

1. Determine \( \gamma = \frac{1}{A} \)
2. \( X = \gamma + \sqrt{\gamma^2 + 1} \)
3. \( \text{VSWR} = \left[ \frac{X^2 + 1}{X^2 - 1} \right]^2 \)

In our amplifier:
\( R = 12.5 \ \Omega \)
\( C = 82 \ \text{pF} \)

This gives:
\( A = 0.784 \)
\( B = 1.029 \)
\( L = 18.62 \ \text{nH} \)
\( \gamma = 1.412 \)
\( X = 3.142 \)
\( \text{VSWR} = 1.138 \)
