Introduction

Most legal expert systems attempt to implement complex models of legal reasoning. Yet the utility of a legal expert system lies not in the extent to which it simulates a lawyer’s approach to a legal problem, but in the quality of its predictions and of its arguments. A complex model of legal reasoning is not necessary: a successful legal expert system can be based upon a simplified model of legal reasoning.

Some researchers have based their systems upon a jurisprudential approach to the law, yet lawyers are patently able to operate without any jurisprudential insight. A useful legal expert system should be capable of producing advice similar to that which one might get from a lawyer, so it should operate at the same pragmatic level of abstraction as does a lawyer—not at the more philosophical level of jurisprudence.

A legal expert system called SHYSTER has been developed to demonstrate that a useful legal expert system can be based upon a pragmatic approach to the law. SHYSTER has a simple representation structure which simplifies the problem of knowledge acquisition. Yet this structure is complex enough for SHYSTER to produce useful advice.

SHYSTER is a case-based legal expert system (although it has been designed so that it can be linked with a rule-based system to form a hybrid legal expert system). Its advice is based upon an examination of, and an argument about, the similarities and differences between cases. SHYSTER attempts to model the way in which lawyers argue with cases, but it does not attempt to model the way in which lawyers decide which cases to use in those arguments. Instead, it employs statistical techniques to quantify the similarity between cases. It decides which cases to use in argument, and what prediction it will make, on the basis of that similarity measure.
SHYSTER is of a general design: it provides advice in areas of case law that have been specified by a legal expert using a specification language, indicating the cases and attributes of importance in those areas. Four different, and disparate, areas of law have been specified for SHYSTER, and its operation has been tested in each of those legal domains.

Testing of SHYSTER in these four domains indicates that it is exceptionally good at predicting results, and fairly good at choosing cases with which to construct its arguments. SHYSTER demonstrates the viability of a pragmatic approach to legal expert system design.  

*    *     *  

SHYSTER is implemented using a dozen modules, written in ISO C.\(^1\) (A breakdown, by module, of the number of lines of C code in SHYSTER is given in figure 1.) This report provides complete code listings of all twelve modules. This code, and the case law specifications used to test SHYSTER, are available on the worldwide web.\(^2\) Full details of the design, implementation, operation and testing of SHYSTER are given elsewhere.\(^3\)
The Shyster module (§1) is the top-level module for the whole system. The Statutes module (§2) is the top-level module for a rule-based system, presently unimplemented. The Cases module (§3) is the top-level module for the case-based system. The Tokenizer and Parser modules (§4 and §5) tokenize and parse a program written in Shyster’s case law specification language. The Dumper module (§6) displays the information that has been parsed. The Checker module (§7) checks for evidence of dependence between the attributes. The Scales module (§8) determines the weight of each attribute. The Adjuster module (§9) allows the legal expert to adjust the weights of the attributes. The Consultant module (§10) interrogates the user as to the attribute values in the instant case. The Odometer module (§11) determines the distances between the leading cases and the instant case, and the Reporter module (§12) writes Shyster’s legal opinion.

*      *      *

The format used for the display of C code in this report is based on that of the CWEB system. Reserved words and preprocessor commands are set in boldface type. Identifiers are set in italics. String constants and character constants are set in a typewriter font, with “\(\text{\textbackslash n}\)” representing a space. Some operators are represented by special symbols, as explained in figure 2.

---

Figure 2: Special symbols used in the listings of C code that appear in this report. The operators on the left are represented by the symbols on the right.

\[
\begin{align*}
\rightarrow & \quad \text{structure/union pointer} & \rightarrow \\
\ast & \quad \text{indirection} & \ast \\
\ast & \quad \text{multiplication} & \times \\
== & \quad \text{equal to} & \equiv \\
\neq & \quad \text{not equal to} & \neq \\
\leq & \quad \text{less than or equal to} & \leq \\
\geq & \quad \text{greater than or equal to} & \geq \\
! & \quad \text{logical negation} & \neg \\
\&\& & \quad \text{logical AND} & \land \\
\mid \mid & \quad \text{logical OR} & \lor
\end{align*}
\]
SHYSTER’s external identifiers are made up of upper- and lower-case letters. Static identifiers consist only of lower-case letters. Identifiers in all upper-case are enumerated identifiers and other constants.

An index to all of the identifiers which appear in the code listings, and which are not reserved words or preprocessor commands, is at the end of this report.

*   *   *

Much of SHYSTER’s output is in \LaTeX{} format: i.e. it is suitable for processing by the \LaTeX{} document processor.\(^6\) This contributes to SHYSTER’s portability, as \LaTeX{} is widely available on many platforms. Using \LaTeX{} simplifies the foot-noting of text (\texttt{\footnote{...}}), allows some data to be displayed in a clear and economical tabular format (\texttt{\begin{tabular}...}), and ensures the aesthetic quality of the output.

---

\(^2\)\url{http://cs.anu.edu.au/software/shyster}

\(^3\)Popple 1993, 1996.

\(^4\)Knuth and Levy 1994. CWEB is a version of Knuth’s WEB system (1986a, 1986b) adapted to C. The CWEB system of structured documentation was not used in the development of SHYSTER, but CWEB’s approach to “pretty-printing” C code has been adopted for this report. This report was prepared using the \LaTeX{} document processor; \LaTeX{} code was generated from SHYSTER’s C code using a preprocessor constructed by the author.

\(^5\)All of the special symbols in figure 2 are used by CWEB, except for \texttt{x}: CWEB uses \texttt{*} for both indirection and multiplication.

\(^6\)Lamport 1986 describes \LaTeX{} which is a set of macros for Knuth’s \TeX{} system (1984, 1986a). SHYSTER’s \LaTeX{} output is suitable for processing by \LaTeX{} version 2.09 (25 March 1992) and \TeX{} version 3.141. It can also be processed, in “compatibility mode,” by \LaTeX{} 2\epsilon{} which is described by Lamport 1994.

Bibliography

LAMPORT, Leslie 1986, \texttt{\emph{\LaTeX}}: A Document Preparation System, Addison-Wesley, Reading, Massachusetts. ISBN 0 201 15790 X.
Describes \texttt{\LaTeX} 2.09.

Describes \texttt{\LaTeX} 2ε.

All of the identifiers which appear in the code listings in this report, and which are not reserved words or preprocessor commands, are listed below.

Function names are followed by a pair of parentheses. The names of SHYSTER’s defined types are marked with a star.

SHYSTER’s external identifiers are made up of upper- and lower-case letters; its static identifiers consist only of lower-case letters. Identifiers in all upper-case are enumerated identifiers and other constants.

Page numbers set in boldface type refer to definitions of functions or constants, or to declarations of types or variables (including structure member declarations). Page numbers set in italics refer to function declarations.

Where an identifier is defined in an ISO C standard library, the name of that library appears in angle brackets.
