Convergence Rate of Optimal Periodic Gossiping on Ring Graphs

S. Mou A. S. Morse B. D. O. Anderson

Abstract—In an $n$-node connected graph $\mathcal{A}$, each node $i$ is with a real-valued state $x_i(t), i = 1, 2, \ldots, n$, and is able to communicate with certain other nodes. A periodic gossip sequence is able to drive all $x_i(t)$ to converge to $\frac{1}{n} \sum_{i=1}^{n} x_i(0)$ exponentially fast. Different sequences are usually associated with different convergence rates for graphs with cycles. This paper mainly focuses on a type of optimal periodic gossip sequences for ring graphs. Explicit formulas to compute their convergence rates are given, which are determined by the adjacency matrix of the $\frac{n}{2}$-node ring graph when $n$ is even and Chebychev polynomials of the second kind when $n$ is odd.

I. INTRODUCTION

Increasing interests have been given to sensor networks, which have found extensive applications in surveillance, target tracking, etc [1]–[3]. Each node in a sensor network usually controls a state initialized by a real-valued measurement and is able to communicate with certain other sensor nodes called its “neighbors”. Since these measurements in practice are usually with zero-mean noise, it is meaningful to develop methods for each node to achieve the global average, which is the average of initial state values of all nodes across the network, by only communications among neighbors. Such methods are often referred as to distributed averaging algorithms [4]–[8], which are special types of distributed consensus algorithms [9]–[17].

One type of distributed averaging algorithms is the Metropolis Algorithm [18], in which each node update its state value to be a weighted average of states of all its neighbors at each iteration. Implementation of this algorithm usually requires each node to be able to broadcast and at least know an upper bound of degrees of all its neighbors. Another popular type of distributed algorithms are gossiping algorithms [19]–[21], in which one pair of nodes gossip at each iteration by updating their state values to the average of their previous ones. Thus in a gossiping algorithm each node is only required to communicate with one node instead of broadcasting. To enable more than one disjoint pairs of nodes to gossip at each time with the goal of potentially speeding up the convergence, periodic gossiping algorithms are recently studied in [22], which involve a periodic gossip sequence such that one pair of nodes gossip just once over one period. Convergence rate of such a periodic gossiping is determined by the magnitude of the second largest eigenvalue of a matrix associated with the gossip sequence occurring over one period. When the underlying graph is a tree, the convergence rate does not change with respect to the order of gossiping [23], [24], which is usually not true when it comes to graphs with cycles.

In this paper we study periodic gossip sequences which allow gossips of disjoint node pairs to take place simultaneously in one step inspired by [25]. If the period of a periodic gossip sequence is equal to $\chi(\mathcal{A})$, the chromatic index of the network $\mathcal{A}$, we call it an optimal periodic gossip sequence. By optimal is meant that one of its period requires the minimal number of steps for implementation. Given the network is connected, all optimal period gossiping sequences drive each node’s state to converge to the global average as fast as $\rho$ converges to 0, where $\rho$ is called the convergence rate and is related to the second largest eigenvalue in magnitude of a matrix. A major contribution of this paper is to obtain explicit formulas for the convergence rate $\rho$ for optimal periodic gossip sequences when $\mathcal{A}$ is a ring graph. Especially when $\mathcal{A}$ is a $n$-node ring graph with $n$ even, the convergence rate $\rho$ is determined by the adjacency matrix of the $\frac{n}{2}$-node ring graph, which implies that $\rho$ is fixed as long as the number of nodes in a ring graph is fixed. When $\mathcal{A}$ is a $n$-node ring graph with $n$ odd, we find that $\rho$ is related to Chebychev polynomials of the second kind.

The remainder of this paper is organized as follows: We formulate the problem of solving distributed averaging problem using optimal periodic gossiping and present our main result in Section II. Proof of all theorems will be given in Section III. Then we conclude in Section IV.

II. PROBLEM FORMULATION AND MAIN RESULT

Consider a network of $n$ sensor nodes, in which each node $i$ controls a real-valued state $x_i(t) \in \mathbb{R}$ and is able to communicate with certain other nodes called its neighbors. Suppose the neighbor relationship of the network can be characterized by a connected undirected graph $\mathcal{A}$ such that there is an edge $(i, j) \in \mathcal{E}$ if and only if node $i$ and $j$ are neighbors, where $\mathcal{E}$ denotes the edge set of $\mathcal{A}$.

The goal of gossiping algorithms is to enable each node to achieve the global average $\frac{1}{n} \sum_{i=1}^{n} x_i(0)$ by letting one pair of neighbor nodes gossip at each time step, namely, updating their state values to be the average of their previous ones while all other agents’ states remain unchanged. We use a gossip sequence $\mathbf{E} = e_1, e_2, \ldots, e_m$ to denote the neighbor node pairs gossiping in order, where each $e_k = (i_k, j_k) \in \mathcal{E}$. The research of A. S. In this paper, we only consider the infinite periodic gossip sequence \( E, E, E, \ldots \). Its period is denoted by \( T \), which is the number of steps needed to implement its one-period subsequence \( E \). Suppose each edge in \( \mathcal{A} \) only appears once in one period \( E \). If only one gossip is allowed at one time step, \( T \) is equal to the number of edges in \( E \). When a subset of edges are such that no two edges are adjacent to the same node, these edges are said to be disjoint and the gossips on these edges can be performed simultaneously in one time step, which is called multi-gossip. In this case the minimum value of \( T \) is related to an edge-coloring problem on \( \mathcal{A} \).

In graph theory, edge coloring is an assignment of different colors to the edges of a graph \( \mathcal{A} \) such that no two edges sharing a common node have the same color. The minimum number of colors needed in an edge coloring problem is called the chromatic index denoted by \( \chi'(\mathcal{A}) \) [26]. Note that \( \chi'(\mathcal{A}) = d_{\text{max}} \) or \( d_{\text{max}} + 1 \), where \( d_{\text{max}} \) is the maximum degree of a graph.

When multi-gossip is allowed, a periodic gossip sequence \( E, E, E, \ldots \) with \( T = \chi'(\mathcal{A}) \) is called an optimal periodic gossip sequence in the sense that one period of such sequence requires a minimal number to implement. It can be easily shown that optimal periodic gossip sequence drive all \( x_i(t) \) to converge to \( \frac{1}{2} \sum_{i=1}^{n} x_i(0) \) as fast as \( \rho^n \) converges to 0. Here, \( \rho \) is called the convergence rate of periodic gossip sequences, which is equal to the second largest eigenvalue in magnitude of a matrix as shown later. When \( \mathcal{A} \) is a tree graph, all optimal periodic gossip sequences share the same convergence rate by results in [22]-[24], which however are usually not true for graphs with cycles. To explore more about convergence rate invariance and obtain explicit formulas for computing \( \rho \), we focus on the case when \( \mathcal{A} \) is a ring graph with the node set \{1, 2, ..., \( n \)\} and the edge set \{(1, 2), (2, 3), ..., (n - 1, n), (n, 1)\}.

When \( n \) is even, the chromatic index \( \chi'(\mathcal{A}) = 2 \) and \( \mathcal{A} \) is uniquely 2-colorable graph, that is, \( \mathcal{E} \) can be uniquely divided into two disjoint sets \( \mathcal{E}_1 = \{(1, 2), (3, 4), \ldots, (n - 1, n)\} \) and \( \mathcal{E}_2 = \{(2, 3), (4, 5), \ldots, (n - 2, n - 1), (n, 1)\}\). In this case we have the following result:

**Theorem 1:** When \( \mathcal{A} \) is an \( n \)-node ring graph with \( n \) even and \( n \geq 4 \), all optimal periodic gossip sequences share the same convergence rate

\[
\rho = \cos^2 \frac{2\pi}{n} \tag{1}
\]

In the case that \( \mathcal{A} \) is an \( n \)-node ring graph with \( n \) an odd integer, the chromatic index \( \chi'(\mathcal{A}) = 3 \). Note that \( \mathcal{A} \) is not uniquely 3-colorable in this case. Take the 9-node ring graph for example, the edge set \( \mathcal{E} \) can be the union of three disjoint sets \( \mathcal{E}_1 = \{(1, 2), (3, 4), (5, 6), (7, 8)\} \), \( \mathcal{E}_2 = \{(9, 1)\} \) and \( \mathcal{E}_3 = \{(2, 3), (4, 5), (6, 7), (8, 9)\} \), or the union of \( \mathcal{E}_1 = \{(1, 2), (4, 5), (7, 8)\} \), \( \mathcal{E}_2 = \{(2, 3), (5, 6), (8, 9)\} \) and \( \mathcal{E}_3 = \{(3, 4), (6, 7), (9, 1)\} \). Optimal periodic gossip sequences corresponding to these two types of edge coloring usually do not share the same convergence rate. To get similar result to Theorem 1, we limit ourselves to a special type of optimal periodic gossip sequences corresponding to the edge coloring such that the edge set of \( \mathcal{A} \) is the union of three disjoint sets \( \mathcal{E}_1 = \{(2, 3), (4, 5), \ldots, (n - 1, n)\} \), \( \mathcal{E}_2 = \{(n, 1)\} \) and \( \mathcal{E}_3 = \{(1, 2), (3, 4), \ldots, (n - 2, n - 1)\} \). We call these sequences optimal periodic gossip sequences of type 1. Then we have the following result:

**Theorem 2:** When \( \mathcal{A} \) is an \( n \)-node ring graph with \( n \) an odd integer and \( n \geq 3 \), all optimal periodic gossip sequences of type 1 share the same convergence rate \( \rho \), which is the 2nd largest of \( \{\lambda : \lambda = \frac{\pi^2}{q^2}, \ 2(q+1)(U_{n-1} - U_{n-3}) - q - 3 = 0\} \), where \( U_k(q) \) are Chebyshev polynomials of the second kind defined as

\[
\begin{align*}
U_0(q) & = 1 \\
U_1(q) & = 2q \\
U_k(q) & = 2qU_{k-1}(q) - U_{k-2}(q), \ k \geq 2
\end{align*}
\]

**Remark 1:** Note that Chebyshev polynomials play a significant role in almost every area of numerical analysis including polynomial approximation, numerical integration, spectral methods for partial differential equations [27]. The finding in this paper may give us a clue to bridge the connection between convergence rate of optimal periodic gossip sequences and Chebyshev polynomials for more general graphs.

III. Analysis

To prove Theorem 1-2, we will first derive an evolution model in state space. Toward to this end, we define a primitive gossip matrix \( P_{ij} = [p_{kl}]_{n \times n} \) for each gossip step \( (i, j) \) with entries defined as

\[
p_{kl} = \begin{cases}
\frac{1}{2}, & (k, l) \in \{(i, i), (i, j), (j, i), (j, j)\}; \\
1, & k = l, k \neq i, k \neq j; \\
0, & \text{otherwise}.
\end{cases}
\]

For a gossip sequence \( (i_1, j_1), (i_2, j_2), \ldots, (i_k, j_k) \), we define the corresponding gossip matrix as

\[
P_{i_1j_1} \cdots P_{i_kj_k} P_{i_1j_1}
\]

Let \( x(t) = [x_1(t) \ x_2(t) \ \cdots \ x_n(t)]' \). If \( i \) and \( j \) gossip at time \( t + 1 \), one has

\[
x(t + 1) = P_{ij} x(t), \ t \geq 0 \tag{2}
\]

For a periodic gossip sequence \( E, E, \ldots, E \) with period \( T \), we let \( W \) be the gossip matrix corresponding to \( E \). Then

\[
x((k + 1)T) = Wx(kT), \ k = 0, 1, 2, \ldots
\]

It follows that

\[
x(kT) = W^k x(0), \ k = 0, 1, 2, \ldots \tag{3}
\]
By (3) one has
\[ x(kT) - \frac{1}{n} \sum_{i=1}^{n} x_i(0) \mathbf{1} = W^k x(0) - \frac{11'}{n} x(0) \]
\[ = W^k (I - \frac{11'}{n}) x(0) \]
\[ = W^k (I - \frac{11'}{n})^k x(0) \]
\[ = (W - \frac{11'}{n})^k x(0) \]
where \( I \) is the \( n \times n \) identity matrix and \( \mathbf{1} \) is the \( n \times 1 \) vector with all elements equal to 1s. By results in [22], one has \(|\lambda_2(W)| < 1 \) and \( \lambda_1(W - \frac{11'}{n}) = \lambda_2(W) \), where \( \lambda_i(W) \) denote the \( i \)th largest eigenvalue in magnitude of matrix \( W \). Thus \(|x(kT) - \frac{1}{n} \sum_{i=1}^{n} x_i(0) \mathbf{1}| \) converges to 0 as fast as \( \rho^k \) converges to 0, where \( \rho = |\lambda_2(W)| \). Then all \( x_i(t) \) converge to \( \frac{1}{n} \sum_{i=1}^{n} x_i(0) \) as fast as \( \rho^T \) converges to 0.

**Proof of Theorem 1:** Let \( W \) be the gossip matrix corresponding to one-period subsequence of any optimal periodic gossip sequence on \( \mathcal{A} \). Let \( W_0 \) be the gossip matrix corresponding to one specific such sequence

\[ \mathbf{E} = \mathbf{E}_1, \mathbf{E}_2 \]

where \( \mathbf{E}_1 = (2,3),..., (n-2,n-1), (n,1) \) and \( \mathbf{E}_2 = (1,2),(3,4),..., (n-1,n) \). To prove all optimal periodic gossip sequences share the same convergence rate, it is sufficient to show that

\[ cp(W) = cp(W_0) \quad (4) \]

where \( cp(\cdot) \) denotes the characteristic polynomial of a matrix. Let \( S_i \) denote the gossip matrix corresponding to \( \mathbf{E}_i \), \( i = 1,2 \). Then

\[ W_0 = S_2 S_1 \]

Since \( \mathcal{A} \) is uniquely 2-colorable, one period of any optimal periodic gossip sequence must be either \( \pi_1(\mathbf{E}_1), \pi_2(\mathbf{E}_2) \) or \( \pi_2(\mathbf{E}_2), \pi_1(\mathbf{E}_1) \), where \( \pi_i(\mathbf{E}_i) \) is a permutation of the gossip sequence \( \mathbf{E}_i \), \( i = 1,2 \). Let \( S_i \) denote the gossip matrix corresponding to the gossip sequence \( \pi_i(\mathbf{E}_i) \). Then

\[ W = \tilde{S}_1 \tilde{S}_2 \]
or

\[ W = \tilde{S}_2 \tilde{S}_1 \]

Note that all edges in \( \mathbf{E}_i \) are disjoint, then

\[ S_i = \tilde{S}_i, \quad S'_i = S_i, \quad i = 1,2 \]

Then

\[ cp(\tilde{S}_1 \tilde{S}_2) = cp(\tilde{S}_2 \tilde{S}_1) = cp(S_2 S_1) \]

Thus (4) is true.

Next we show the eigenvalues of \( W_0 \) are those in

\[ 0, \cos^2 \frac{2k\pi}{n}, k = 0,1,2,..., \frac{n}{2} - 1 \quad (5) \]

\(^1\)Key idea of the analytical proof for (5) was initially from discussions with Steve Butler at Iowa State University.

We first check the case when \( n = 4 \), in which one has

\[ W_0 = \frac{1}{4} \begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 \end{bmatrix} \]

the eigenvalues of which are \( \{0,1\} \). Then (5) is true.

When \( n \) is even and \( n \geq 6 \), we let \( e_k \) denote the \( k \)th column of the \( n \times n \) identity matrix, \( k = 1,2,...,n \). One has \( e_i e_j = 1 \) if \( i = j \) and \( e_i e_j = 0 \) otherwise. Then

\[ W_0 = (P_{n(1,2)}(P_{n(1,3)}(P_{n(2,3)}(P_{n(1,4)}(P_{n(1,5)}(P_{n(1,6)}(P_{n(1,n-1)}(P_{n(1,n-2)}(P_{n(1,n-1})))))))))) \]

\[ = \frac{1}{2} \begin{bmatrix} e_1' + e_n' \\ e_1' + e_2' + e_3' \\ e_1' + e_2' + e_3' + e_4' \\ e_2' + e_3' + e_4' + e_5' \\ \vdots \\ e_1' + e_2' + e_3' + e_4' + e_5' \end{bmatrix} \quad \frac{1}{2} \begin{bmatrix} e'_n/2 + e'_n-1 \\ e'_n/2 + e'_n-1 + e'_n \\ e'_n/2 + e'_n-1 + e'_n \\ e'_n/2 + e'_n-1 + e'_n \\ \vdots \end{bmatrix} \quad n \times n \]

Note that 0 is an eigenvalue of \( W_0 \) with \( \frac{n}{2} \) left eigenvectors

\[ e_1' - e_2', e_3' - e_4',..., e'_{n-1} - e'_n \quad (6) \]

Let \( \lambda \) denote any non-zero eigenvalues of \( W_0 \) and let \( v \) denote any right eigenvector of \( W_0 \) associated with the eigenvalue \( \lambda \). Then \( v \) is perpendicular to all vectors defined in (6). Let \( r = \frac{n}{2} \). Then \( v \) must be in the form

\[ v = [v_1, v_1, v_2, v_2, \cdots, v_r, v_r]' \]

where \( v_j, j = 1,...,r \) are scalars. Thus

\[ W_0 v = \frac{1}{4} \begin{bmatrix} v_r + 2v_1 + v_2 \\ v_r + 2v_1 + v_2 \\ v_1 + 2v_2 + v_3 \\ \vdots \end{bmatrix} = \lambda v \quad (7) \]

Let \( \bar{v} = [v_1, v_2, \cdots, v_r]' \). Let

\[ W_0 \bar{v} = \frac{1}{4} (2I + A_r) \quad (8) \]

where \( A_r \) denotes the adjacency matrix of the \( r \)-node ring graph with edges \{ \{(1,2),(2,3),...,(r-1,r),(r,1)\} \). By (7) and (8) one has

\[ W_0 \bar{v} = \lambda \bar{v} \]

All non-zero eigenvalues of \( W_0 \) are eigenvalues of \( W_0 \). Note that \( W_0 \) is a circulant matrix with first column \( c_0 = \)
where $E_1 = \{ (2,3), (4,5), \ldots, (n-1,n) \}$, $E_2 = (n,1)$ and $E_3 = (1,2), (3,4), \ldots, (n-2,n-1)$. To prove all optimal periodic gossip sequences of type 1 share the same convergence rate, it is sufficient to show that

$$\text{cp}(W) = \text{cp}(W_0)$$

Note that

$$W_0 = S_3 S_2 S_1$$

Let $S_i$ denote the gossip matrix corresponding to one specific sequence $S_i$, $i = 1, 2, 3$. Then

$$W = \bar{S}_k \bar{S}_{k_2} \bar{S}_{k_3}$$

where $k_1, k_2, k_3$ is a permutation of 1, 2, 3. Note that all edges in $S_i$ are disjoint, then

$$S_i = S_i', S_i'' = S_i, \quad i = 1, 2, 3$$

By (11) and (12), one has

$$\text{cp}(W) = \text{cp}(S_k, S_{k_2}, S_{k_3})$$

Note that $S_1, S_2, S_3$ are symmetric matrices. Then

$$\text{cp}(S_1 S_2 S_3) = \text{cp}(S_3 S_2 S_1)$$

In addition note that,

$$\text{cp}(S_1 S_2 S_3) = \text{cp}(S_2 S_3 S_1) = \text{cp}(S_3 S_1 S_2)$$

$$\text{cp}(S_3 S_2 S_1) = \text{cp}(S_2 S_1 S_3) = \text{cp}(S_1 S_3 S_2)$$

Then

$$\text{cp}(S_1 S_2 S_3) = \text{cp}(S_k S_{k_2} S_{k_3})$$

Thus $\text{cp}(W) = \text{cp}(W_0)$.

Next we show the eigenvalues of $W_0$ are determined by Chebychev polynomials of second kind. For $n = 3$, one has

$$E = (2,3), (3,1), (1,2)$$

and

$$W_0 = \frac{1}{8} \begin{bmatrix} 2 & 3 & 3 \\ 2 & 3 & 3 \\ 4 & 2 & 2 \end{bmatrix}$$

Non-zero eigenvalues of $W_0$ are $\{1, -\frac{1}{8}\}$. Note that $2(q+1)/U_1(q) - U_0(q)] - q - 3 = 4q^2 + q - 5 = (4q+5)(q-1).$

Thus the set of all non-zero eigenvalues of $W_0$ is $\lambda : \lambda = 2^{\pm 1}, 2(q+1)/U_1(q) - U_0(q)] - q - 3 = 0 \{1, -\frac{1}{8}\}$. Theorem 2 is true for $n = 3$. For $n = 5$, one has $E = (2,3), (4,5), (5,1), (1,2), (3,4)$ and

$$W_0 = \frac{1}{8} \begin{bmatrix} 2 & 2 & 2 & 1 & 1 \\ 2 & 2 & 2 & 1 & 1 \\ 0 & 2 & 2 & 2 & 2 \\ 0 & 2 & 2 & 2 & 2 \\ 4 & 0 & 0 & 2 & 2 \end{bmatrix}$$

Non-zero eigenvalues of $W_0$ are $\{1, \frac{1}{8} \pm \frac{1}{8} \}$. Theorem 2 is true for $n = 5$.

For $n$ is odd and $n \geq 7$, one has $E = (2,3), (4,5), \ldots, (n-1,n), (n,1), (1,2), (3,4), \ldots, (n-2,n-1). Let \epsilon_k$ denote the k'the column of the $n \times n$ identity matrix, $k = 1, 2, \ldots, n$. Then the complete gossip matrix is

$$W = \frac{1}{4} \begin{bmatrix} e'_1 + e'_2 & e'_3 & e'_4 & e'_5 & e'_6 & e'_7 & e'_8 & e'_9 & e'_10 \\ e'_1 + e'_2 & e'_3 & e'_4 & e'_5 & e'_6 & e'_7 & e'_8 & e'_9 & e'_10 \\ e'_1 + e'_2 & e'_3 & e'_4 & e'_5 & e'_6 & e'_7 & e'_8 & e'_9 & e'_10 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ e'_1 + e'_2 & e'_3 & e'_4 & e'_5 & e'_6 & e'_7 & e'_8 & e'_9 & e'_10 \end{bmatrix}$$

Then $0$ is an eigenvalue of $W_0$ with $\frac{n-1}{n}$ left eigenvectors

$$e'_1 - e'_2, e'_3 - e'_4, \ldots, e'_{n-2} - e'_{n-1}$$

Let $\lambda$ denote any non-zero eigenvalues of $W_0$ and let $v$ denote any right eigenvector of $W_0$ associated with the
eigenvalue $\lambda$. Then $v$ is perpendicular to all vectors defined in (15). Let $r = \frac{n-1}{2}$. Then $v$ must be in the form of

$$v = \begin{bmatrix} v_1 & v_2 & v_3 & \cdots & v_r & v_{r+1} \end{bmatrix}^T$$

Then

$$W_0v = \frac{1}{8} \begin{bmatrix} 4v_1 + 2v_2 + v_r + v_{r+1} \\ 4v_1 + 2v_2 + v_r + v_{r+1} \\ 2v_1 + 4v_2 + 2v_3 \\ 2v_1 + 4v_2 + 2v_3 \\ 2v_2 + 4v_3 + 2v_4 \\ 2v_2 + 4v_3 + 2v_4 \\ \vdots \\ 2v_{r-1} + 4v_r + 2v_{r+1} \\ 2v_{r-1} + 4v_r + 2v_{r+1} \\ 4v_1 + 2v_2 + v_r + v_{r+1} \end{bmatrix} = \lambda v$$

where $v_i, \ i = 1, \ldots, r+1$ are scalars. Let $\bar{v} = \begin{bmatrix} v_1 & v_2 & \cdots & v_{r+1} \end{bmatrix}^T$. Let $\bar{e}_i$ denote the $i$th column of the $r \times r$ identity matrix, $i = 1, 2, \ldots, r$. Let $A_k$ denote the adjacency matrix of the $k$-node path graph with edges \{$(1,2), (2,3), \ldots, (k-1,k)$\}, $k = 2, 3, \ldots, r$. Let

$$W_0 = \begin{bmatrix} 2A_r + \bar{e}_1\bar{e}_r' & \bar{e}_1 + 2\bar{e}_r \\ 4\bar{e}_1 + 2\bar{e}_r' & -2 \end{bmatrix}_{(r+1) \times (r+1)}$$

Then

$$\frac{1}{8}(W_0 + 4)\bar{v} = \lambda \bar{v} \quad (16)$$

Note that all non-zero eigenvalues of $W_0$ are obtained by shifting and scaling all eigenvalues of $\bar{W}_0$. In the following we’ll try to compute eigenvalues of $W_0$. Toward this end, we let $B_k = pI - 2A_k, 2 \leq k \leq r$. Let $D = B_r - \bar{e}_1\bar{e}_r'$. Let $p$ denote the eigenvalue of $W_0$. Let $cp(W_0)$ denote the characteristic polynomial of $W_0$. Then one has

$$cp(W_0) = det(pI - W_0) = det(\begin{bmatrix} D & b \\ c & a \end{bmatrix})$$

where

$$a = p + 2, \ b = -\bar{e}_1 - 2\bar{e}_r, \ c = -4\bar{e}_1' - 2\bar{e}_r'.$$

By using Schur complement one has

$$cp(W_0) = det(D)(a - cD^{-1}b) \quad (17)$$

To compute (17) we note that

$$cD^{-1}b = 4D^{-1}(1,1) + 2D^{-1}(r,1) + 8D^{-1}(1,r) + 4D^{-1}(r,r) \quad (18)$$

By rank-one permutation, one has

$$D^{-1} = (B_r - \bar{e}_1\bar{e}_r')^{-1} = (I - B_r^{-1}\bar{e}_1\bar{e}_r')^{-1}B_r^{-1} = (I + \frac{B_r^{-1}\bar{e}_1\bar{e}_r'}{1 - \bar{e}_r'B_r^{-1}\bar{e}_1})B_r^{-1} = B_r^{-1} + \frac{B_r^{-1}\bar{e}_1\bar{e}_r'B_r^{-1}}{1 - \bar{e}_r'B_r^{-1}\bar{e}_1} \quad (19)$$

Then

$$D^{-1}(1,1) = B_r^{-1}(1,1) + \frac{B_r^{-1}(1,1)B_r^{-1}(r,1)}{1 - B_r^{-1}(r,1)} \quad (20)$$

$$D^{-1}(1,r) = B_r^{-1}(1,1) + \frac{B_r^{-1}(r,1)^2}{1 - B_r^{-1}(r,1)} \quad (21)$$

$$D^{-1}(r,1) = B_r^{-1}(r,1) + \frac{B_r^{-1}(r,1)B_r^{-1}(1,1)}{1 - B_r^{-1}(r,1)} \quad (22)$$

$$D^{-1}(r,r) = B_r^{-1}(r,1) + \frac{B_r^{-1}(r,1)B_r^{-1}(1,1)}{1 - B_r^{-1}(r,1)} \quad (23)$$

Let

$$T_k = det(B_k) = det(p - 2A_k), \ k = 1, 2, \ldots, r$$

Then

$$B_r^{-1}(1,1) = B^{-1}(r,r) = \frac{T_{r-1}}{T_r} \quad (24)$$

$$B_r^{-1}(1,1) = B^{-1}(r,1) = \frac{2^{-r}}{T_r} \quad (25)$$

Substitute (24) and (25) into (20)-(23), one has Then

$$D^{-1}(1,1) = \frac{T_{r-1}}{T_r - 2^{-r-1}} \quad (26)$$

$$D^{-1}(1,r) = \frac{T_r^2 - 2^{r-2} + 2^{-r-1}T_r}{T_r(T_r - 2^{-r-1})} \quad (27)$$

$$D^{-1}(r,1) = \frac{2^{-r-1}}{T_r - 2^{-r-1}} \quad (28)$$

$$D^{-1}(r,r) = \frac{T_{r-1}}{T_r - 2^{-r-1}} \quad (29)$$

Substituting (26)-(29) into (18) one has

$$cD^{-1}b = \frac{1}{T_r - 2^{-r-1}}[8T_{r-1} + 10 \times 2^{-r-1} + \frac{8T_r^2 - 2^{2r+1}}{T_r}]$$

which and det($D$) = $T_r - 2^{-r-1}, a = p + 2$ and (17) implies

$$cp(W_0) = (p+2)(T_r - 2^{-r-1}) - (8T_{r-1} + 5 \times 2^{-r-1} + \frac{8T_r^2 - 2^{2r+1}}{T_r}) \quad (30)$$

To further simplify (30), we introduce Chebychev polynomials of the second kind as follows

$$U_k(p) = 2pU_{k-1} - U_{k-2}, \ k = 3, 4, \ldots, r \quad (31)$$

with $U_1(p) = 2p$ and $U_2(p) = 4p^2 - 1$. Note that there is a special relation between $U_k(p)$ and the determinant of special matrix, which is

$$U_k(p) = det(2p - A_k)$$

where $A_k$ is the adjacency matrix of the $k$-node path graph with edges \{$(1,2), (2,3), \ldots, (k-1,k)$\}. Then

$$U_k(p) = det(2p - A_k) = 2^{-k}det(p - 2A_k) = 2^{-k}T_k(p) \quad (32)$$

Substitute this into (30) one has

$$cp(W_0) = (p+2)[U_r(p)\frac{p}{4} - \frac{1}{2} - 4U_{r-1}(\frac{p}{4}) + 5 + \frac{U_r^2(p)}{U_r(\frac{p}{4})} - \frac{1}{U_r(\frac{p}{4})}] \quad (32)$$
Let \( q = p^{\frac{1}{4}} \). Then \( q \) is root of
\[
(2q + 1)(2U_r - 1) - (4U_{r-1} + 5 + 2U^2_{r-1} - U_r) = 0. \tag{33}
\]
Note that for Chebychev polynomials of the second kind,
\[
U_{r-1}^2 - 1 = U_r U_{r-2}.
\]
Substituting this into (33) leads to
\[
(2q + 1)U_r - 2U_{r-1} - U_{r-2} - (q + 3) = 0 \tag{34}
\]
By the definition of Chebychev polynomials of the second kind one has
\[
U_r + U_{r-2} = 2qU_{r-1}
\]
Then (34) is simplified to
\[
2(q + 1)(U_r - U_{r-1}) - q - 3 = 0 \tag{35}
\]
From \( \lambda = \frac{1}{2}(p + 4) \) and \( p = 4q \), one has \( \lambda = \frac{1}{2}(q + 1) \). Thus non-zero eigenvalues of \( W_0 \) are
\[
\{ \lambda : \lambda = \frac{1}{2}(q + 1), \ 2(q + 1)(U_r - U_{r-1}) - q - 3 = 0 \}
\]
with \( r = \frac{n-1}{2} \). We complete the proof. \( \square \)

IV. CONCLUSION

In this paper we have studied a type of optimal periodic gossip sequences on ring graphs. Explicit formulas have been given to compute their convergence rates. Simulations suggest that these sequences are with the fastest convergence rate among all periodic gossip sequences on ring graphs though finding analytical proof for this observation is still an open problem. Our future work includes investigating challenging communication issues of implementing periodic gossiping algorithms that may arise from dynamic network topology and unpredictable erasures [28]. We will also consider using the idea of periodic gossiping to develop distributed algorithms for solving linear equations [29]–[31].
