Received November 22, 2007

This paper studies coalgebras from the perspective of finite observations. We introduce the notion of finite step equivalence and a corresponding category with finite step equivalence-preserving morphisms. This category always has a final object, which generalises the canonical model construction from Kripke models to coalgebras. We then turn to logics whose formulae are invariant under finite step equivalence, which we call logics of rank \(\omega\). For these logics, we use topological methods and give a characterisation of compact logics and definable classes of models.

Introduction

Coalgebras for an endofunctor \(T\) on Set encompass many types of state base systems, including Kripke models and frames, labelled transition systems, Moore- and Mealy automata and deterministic systems, see e.g. (Rutten 2000). The research on modal logics as specification languages for coalgebras began with (Moss 1999) and was taken up in e.g. (Kurz 2001c; Rößiger 2001; Rößiger 2000a; Jacobs 1999; Jacobs 2001a).

The relationship between modal logic and coalgebras has been explained in (Kurz 2001a) as follows. If \(Z\) denotes the carrier of the final coalgebra, we can consider the semantics of a modal formula \(\varphi\) as the subset \([\varphi] \subseteq Z\) of states which satisfy \(\varphi\). Intuitively, the elements of \(Z\) are behaviours, and every modal formula \(\varphi\) determines a set of behaviours which satisfy \(\varphi\). In case the logic is \textit{fully expressive} in the sense that it allows us to define \textit{all} subsets of \(Z\), we can identify modal formulae with subsets of \(Z\), resulting in an algebraic approach to investigate modal logics, see (Kurz 2001a; Kurz 2001b).

In general, however, finitary modal logics are not fully expressive. It is the main issue of this paper to present a semantics that adapts the `formulae as subsets of the final coalgebra' idea to the case of finitary logics. We use the so-called \textit{terminal sequence} \((T^n)_{n \in \mathbb{N}}\) of the underlying endofunctor to capture the notion of finitely observable behaviour. The terminal sequence can be understood as approximating the final coalgebra, see (Adámek and Koubek 1995). Intuitively, the elements of the \(n\)-th approximant represent the behaviour that can be observed in \(n\) transition steps. Following (Pattinson 2001; Pattinson 2003), we represent the semantics of a modal formula \(\varphi\) of rank \(n\) as subset \([\varphi]_n \subseteq T^n\).

The terminal sequence also gives rise to a notion of \textit{finite step equivalence}. Intuitively, two processes are \(n\)-step equivalent if they show the same \(n\)-step behaviour, that is, if their projections into \(T^n\) coincide. The main novelty of the paper is the introduction of
the category \( \text{Beh}_\omega(T) \) that has coalgebras as objects and functions that preserve finite step behaviours as morphisms (Section 3). This paper argues that the role of \( \text{Beh}_\omega(T) \) for finitary logics is the same as that of \( \text{Coalg}(T) \) for fully expressive logics. In Section 4, we show that \( \text{Beh}_\omega(T) \) always has a final object, the subsets of which represent formulae of finitary logics. Moreover, we show that the final object in \( \text{Beh}_\omega(T) \) generalises the canonical model construction from Kripke models to coalgebras.

In Section 5, we begin the study of logics whose formulae are invariant under finite step equivalence. These logics are called \textit{logics of rank} \( \omega \). In case that the semantics of every formula \( \varphi \) can be represented as a subset \( [\varphi]_n \subseteq T^n \), \( n < \omega \), we speak of \textit{logics of finite rank}. Whereas fully expressive modal logics allow to express all predicates of the carrier of the final coalgebra, logics of rank \( \omega \) do not in general allow to express all predicates on the final object of \( \text{Beh}_\omega(T) \). This is the reason to consider topologies on coalgebras. The main idea here is that clopen subsets are precisely the predicates which can be expressed through a single formula.

This topology is then used to prove compactness and definability results. Section 6 shows that—assuming the induced sub-logics of formulae of finite rank to be compact and expressive—a logic of finite rank is compact if the functor \( T \) weakly preserves the limit of the finite part \( (T^n)_n \subseteq \omega \) of the terminal sequence. Section 7 characterises classes of coalgebras that are definable by a logic of rank \( \omega \) as being closed under images, subcoalgebras, coproducts and topological closure.

1. Preliminaries and Notation

Throughout the paper, \( T \) denotes an endofunctor on the category of sets and functions. A \( T \)-coalgebra is a pair \( (C, \gamma) \) where \( C \) is a set and \( \gamma : C \rightarrow TC \) is a function. A coalgebra morphism \( f : (C, \gamma) \rightarrow (D, \delta) \) is a function \( f : C \rightarrow D \) such that \( \delta \circ f = Tf \circ \gamma \). The category of \( T \)-coalgebras and coalgebra morphisms is denoted by \( \text{Coalg}(T) \). Given two \( T \)-Coalgebras \( (C, \gamma) \) and \( (D, \delta) \), two states \( c \in C \) and \( d \in D \) are called \textit{behaviourally equivalent}, if they can be identified by a morphism of coalgebras, i.e. if there exists \( (E, \epsilon) \in \text{Coalg}(T) \), \( f : (C, \gamma) \rightarrow (E, \epsilon) \) and \( g : (D, \delta) \rightarrow (E, \epsilon) \) with \( f(c) = g(d) \). If \( \text{Coalg}(T) \) has a final object \( (Z, \zeta) \) and \( !C : (C, \gamma) \rightarrow (Z, \zeta) \) and \( !D : (D, \delta) \rightarrow (Z, \zeta) \) denote the unique morphisms into the final object, this is clearly equivalent to \( !C(c) = !D(d) \). We think of a coalgebra \( (C, \gamma) \) together with a state \( c \) as a process and call \( !C(c) \) its \textit{behaviour}.

\textbf{Example 1.1. (Streams)} For a set \( D \) consider \( TX = D \times X \). Given a coalgebra \( \gamma = \langle \text{head}, \text{tail} : C \rightarrow D \times C \rangle \) the behaviour of an element \( c \in C \) is the infinite list \( \langle \text{head}(c), \text{head}(\text{tail}(c)), \text{head}(\text{tail}(\text{tail}(c))), \ldots \rangle \). Hence, the structure \( (D^\omega, \langle \text{head}, \text{tail} \rangle) \) of infinite lists over \( D \) is final in \( \text{Coalg}(T) \).

\textbf{Example 1.2. (Kripke models)} Suppose \( \text{Prop} \) is a (usually countable) set and \( TX = \mathcal{P}X \times \mathcal{P}\text{Prop} \). Then \( T \)-coalgebras are in 1-1 correspondence with Kripke models and behavioural equivalence coincides with bisimilarity.

We have seen that the final coalgebra defines a notion of behaviour. In general, every state of the final coalgebra represents an infinite amount of information. This paper
suggestions a framework to study finitely observable properties of systems. Hence the final
coalgebra (containing the infinite behaviours of all coalgebras) has to be replaced by
finitary approximations. These approximations are provided by the (finitary part of the)
so-called terminal sequence of the endofunctor $T$.

1.1. The Terminal Sequence

The terminal sequence can be thought of as approximating the final coalgebra. The
following definition has been taken from (Worrell 1999).

The terminal sequence of $T$ is an ordinal indexed sequence of sets $(Z_n)$ together with
a family $(p_n^m)_{m \leq n}$ of functions $p_n^m : Z_n \rightarrow Z_m$ for all ordinals $m \leq n$ such
that

- $Z_{n+1} = TZ_n$ and $p_{n+1}^m = Tp_n^m$ for all $m \leq n$
- $p_n^n = id_{Z_n}$ and $p_k^m = p_k^m \circ p_m^m$ for $k \leq m \leq n$
- the cone $(Z_n, (p_n^m))_{m \leq n}$ is limiting whenever $n$ is a limit ordinal.

Thinking of $Z_n$ as the $n$-fold application of $T$ to the limit $1 = \{0\}$ of the empty
diagram, we write $T^n$ for $Z_n$ in the sequel. Intuitively, $T^n$ represents behaviour that
can be observed in $n$ steps. If, for example $TX = D \times X$, then $T^n \cong D^n$ contains all
lists of length $n$.

Note that every coalgebra $(C, \gamma) \in \text{Coalg}(T)$ gives rise to a cone $(C, (\gamma_n : C \rightarrow T^n1))$ over the
terminal sequence:

**Definition 1.3.** If $(C, \gamma) \in \text{Coalg}(T)$, define $\gamma_n : C \rightarrow T^n1$ to be $T\gamma_m \circ \gamma$, if $n = m + 1$
is a successor ordinal, and the unique map satisfying $\gamma_m = p_n^m \circ \gamma_n$ for all $m < n$, if $n$ is
a limit ordinal.

We will often use without further mentioning the following easy fact:

**Proposition 1.4.** Let $n$ be an ordinal.
1. Let $f : (C, \gamma) \rightarrow (D, \delta)$ be a coalgebra morphism. Then $\delta_n \circ f = \gamma_n$.
2. Let $(C, \gamma) \in \text{Coalg}(T)$. Then $p_n^{n+1} \circ T(\gamma_n) \circ \gamma = \gamma_n$.

2. Introductory Examples

For illustration and motivation of our later development, we discuss two different logics
in detail. The main claim that we want to substantiate is that modal formulae can be
semantically represented as subsets of $T^n1$, where $n$ is the rank of the formula.

2.1. Propositional Modal Logic

This section argues that modal formulae of finite rank, interpreted over coalgebras, have
a natural representation as subsets of some $T^n1$, where $n \in \omega$ is a finite ordinal. We start
by re-considering Example 1.2 and show that a formula of rank $n$ can be represented as
subset of $T^n1$.

Suppose $TX = PX \times P\text{Prop}$. Then $T$-coalgebras are Kripke models, which is why
we use propositional modal logic to describe properties of $T$-coalgebras. We denote the
language of propositional modal logic by $\mathcal{ML}$, that is, $\mathcal{ML}$ is the least set according to the grammar

$$\mathcal{ML} \ni \varphi, \psi := \text{ff} | p | \varphi \rightarrow \psi | \Box \varphi$$

where $p \in \text{Prop}$ ranges over the set of atomic propositions.

Given a $T$-coalgebra $(C, \gamma)$, the semantics $[\varphi]_C \subseteq C$ of a modal formula $\varphi \in \mathcal{ML}$ is then inductively defined by

- $[\text{ff}] = \emptyset$
- $[p] = \{ c \in C | p \in \pi_2 \circ \gamma(c) \}$
- $[\varphi \rightarrow \psi] = (C \setminus [\varphi]) \cup [\psi]$
- $[\Box \varphi] = \{ c \in C | \pi_1 \circ \gamma(c) \subseteq [\varphi] \}$

This definition is a coalgebraic formulation of the standard semantics of propositional modal logic (cf. e.g. (Goldblatt 1992)). Given a formula $\varphi \in \mathcal{ML}$, the rank of $\varphi$, which represents the nesting depth of $\Box$-operators, is then given inductively by $\text{rank}(\text{ff}) = 0$, $\text{rank}(\varphi \rightarrow \psi) = \max\{\text{rank}(\varphi), \text{rank}(\psi)\}$, $\text{rank}(p) = 1$ for $p \in \text{Prop}$, $\text{rank}(\Box \varphi) = \text{rank}(\varphi) + 1$.

Semantically, the rank can be thought of as the number of transition steps a formula contains information about. A similar intuition applies to the approximants $T^n$ of the endofunctor: we think of predicates on $T^n$ as representing behaviour that can be observed in $n$ transition steps. The following proposition makes this relationship precise:

**Proposition 2.1.** Suppose $\varphi \in \mathcal{ML}$ has rank $n$. Then there exists $t \subseteq T^n$ such that $[\varphi]_C = \gamma_n^{-1}(t)$ for all $(C, \gamma) \in \text{Coalg}(T)$.

**Proof.** By induction on the structure of formulae: For $\varphi = \text{ff} \text{ evidently } [\varphi] = \gamma_0^{-1}(0)$. For the case $\varphi = p$ for $p \in \text{Prop}$ let $t = \{(X, Y) | X \subseteq 1, Y \subseteq \text{Prop}, p \in Y \subseteq T1$. Then $[p] = \gamma_1^{-1}(t)$. If $\varphi, \psi \in \mathcal{ML}$ with $\text{rank}(\varphi) = n$, $\text{rank}(\psi) = m$, put $k = \max\{n, m\}$ and assume that $[\varphi] = \gamma_n^{-1}(t)$, $[\psi] = \gamma_m^{-1}(s)$. For $u = (T^k \setminus (p_k)^{-1}(t)) \cup (p_k)^{-1}(s) \subseteq T^k$, the fact that $(C, (\gamma_n))$ is a cone over the terminal sequence implies that $[\varphi \rightarrow \psi] = \gamma_k^{-1}(u)$.

For the most interesting case $\varphi = \Box \psi$ consider the operation defined by

$$\lambda(X)(y) = \{(x', a) \in \mathcal{P}(X) \times \mathcal{P}(\text{Prop}) | x' \subseteq x \}$$

where $X$ is a set and $x \subseteq X$. An easy calculation shows that we can rephrase the semantics of the $\Box$-operator as $[\Box \psi] = \gamma^{-1} \circ \lambda(C)([\psi])$. Now assume that $\psi$ has rank $n$ with $[\psi] = \gamma_n^{-1}(s)$. Put $t = \lambda(T^n)(s)$. Then $[\Box \psi] = \gamma_n^{-1}(t)$ follows from the fact that $\lambda : 2 \rightarrow 2 \circ T$ is a natural transformation, where 2 denotes the contravariant powerset functor. \hfill $\Box$

**Remark 2.2.** We have seen that formulae of rank $n$ correspond to subsets of $T^n$ of the terminal sequence of $T$. This generalises from $TX = \mathcal{P}X \times \mathcal{P}\text{Prop}$ to arbitrary functors $T : \text{Set} \rightarrow \text{Set}$. Indeed, in the proof of the above proposition, we only used the fact that atomic propositions can be represented as subsets of $T^n$ and that the semantics of the $\Box$-operator can be formulated in terms of a natural transformation $2 \rightarrow 2 \circ T$.

Such natural transformations are often called predicate liftings and have been used by a number of authors (Rößiger 2001; Rößiger 2000a; Jacobs 1999; Jacobs 2001a) to describe the semantics of modal logics over coalgebras. We thus obtain a wealth of examples for
arbitrary endofunctors \( T \) if we consider modal logics where atomic propositions can be represented as subsets of \( T1 \) and modal operators are interpreted using predicate liftings (see (Pattinson 2001) for more information).

2.2. Linear Temporal Logic on Streams

Linear temporal logic \( \mathcal{LTL} \) (see e.g. (Kröger 1987; Manna and Pnueli 1992)) is a temporal logic to describe properties of infinite runs of programs, i.e. streams. We use \( T \)-coalgebras for \( TX = X \times S \) Prop (cf. Example 1.1), with \( S \) countably infinite, as semantics. This is a slight deviation from the standard semantics which is given in terms of infinite sequences of subsets of \( \text{Prop} \). The language \( \mathcal{LTL} \) of linear temporal logic is the least set according to the grammar

\[
\mathcal{LTL} \ni \varphi, \psi ::= \text{ff} \mid p \mid \varphi \rightarrow \psi \mid \varrho \varphi \mid \Box \varphi
\]

where \( p \in \text{Prop} \) ranges over the set of atomic propositions. We read \( \varrho \) as ‘next’ and \( \Box \) as ‘always’. Given a \( T \)-coalgebra \((C, \gamma)\), we define the semantics \([\varphi]_C = [\varphi]_{\gamma_1}\) of an \( \mathcal{LTL} \)-formula \( \varphi \) inductively by

\[
[\varrho \varphi] = \{ c \in C \mid \pi_1 \circ \gamma(c) \in [\varphi] \} \quad \text{ and } \quad [\Box \varphi] = \bigcap_{n < \omega} [\varrho^n \varphi]
\]

where \( \varrho^n \) stands for a sequence of \( n \) “\( \varrho \)” and the semantics of boolean operators and atomic propositions is as in the previous example. In contrast to the previous example, not all formulae can be represented as subsets of some approximant \( T^1 \):

**Example 2.3.** Let \( p \in \text{Prop} \) and \( \varphi = \Box p \). Then there is no \( n < \omega \) and \( t \subseteq T^1 \) with \([\varphi]_C = \gamma_1^{-1}(t)\) for all \((C, \gamma) \in \text{Coalg}(T)\).

We can, however, represent every formula as subset of \( T^1 \cong (\mathcal{P} \text{Prop})^\omega \).

**Proposition 2.4.** For all \( \varphi \in \mathcal{LTL} \) there is \( t \subseteq T^1 \) such that \([\varphi]_C = \gamma_1^{-1}(t)\).

**Proof.** Consider \((K, \kappa) = ((P \text{Prop})^\omega, (\text{head}, \text{tail}))\). Then \( K \cong T^1 \) and \([\varphi]_C = \gamma_1^{-1}([\varphi]_K)\).

3. Finite Step Equivalence and the Category \( \text{Beh}_n(T) \)

The previous section has shown that, for logics interpreted via predicate liftings as described in Remark 2.2, formulae of finite rank can be represented as subsets of the elements \( T^1 \) of \( T \)'s terminal sequence. For the remainder of the exposition, we take a semantical view and take subsets of the \( T^1 \) as representing formulae of finite rank; this allows us to consider logics for coalgebras in broad generality without making a commitment to any particular syntax.

We begin with introducing a notion of equivalence on states which reflects the fact that two states cannot be distinguished by a predicate of finite rank.

**Definition 3.1.** Let \( n \) be an ordinal and suppose \((C, \gamma), = (D, \delta) \in \text{Coalg}(T)\). For \( c \in C \) we call \( \gamma_n(c) \) the \( n \)-step behaviour of \( c \).
1 Two states \((c, d) \in C \times D\) are called \(n\)-step equivalent, denoted by \(c \sim_n d\), if \(\gamma_n(c) = \delta_n(d)\). We call \(c\) and \(d\) finite step equivalent if \(c \sim_n d\) for all \(n < \omega\).

2 The systems \((C, \gamma)\) and \((D, \delta)\) are \(n\)-step equivalent, denoted by \((C, \gamma) \sim_n (D, \delta)\), if \(\gamma_n(C) = \delta_n(D)\). They are called finite step equivalent, denoted by \((C, \gamma) \sim_{<\omega} (D, \delta)\), if \((C, \gamma) \sim_n (D, \delta)\) for all \(n < \omega\).

Under the assumption that the final coalgebra exists, two states of coalgebras are behaviourally equivalent, if they are identified by the unique morphism into the final coalgebra. As shown in (Adámek and Koubek 1995), this is equivalent to \(\gamma_n(x) = \gamma_n(y)\) for all ordinals \(n\). Finite step equivalence, as introduced above, restricts the validity of this equation to finite ordinals. Note that \(c, d\) are finite step equivalent if \(c \sim \omega \ d\). In the context of modal logic, that is, for \(TX = \mathcal{P}X \times \mathcal{PProp}\), finite step equivalence is (a slight variation of) the bounded bisimulation of modal logic as studied in (Gerbrandy 1999).

The next proposition clarifies on the relationship between finite step equivalence and behavioural equivalence on states of coalgebras:

**Proposition 3.2.** Suppose \((C, \gamma), (D, \delta) \in \text{Coalg}(T)\) and \((c, d) \in C \times D\).

1 If \(c\) and \(d\) are behaviourally equivalent, then they are finite step equivalent.

2 If \(T\) is \(\omega\)-accessible, then \(c\) and \(d\) are behaviourally equivalent if and only if they are finite step equivalent.

**Proof.** The first claim is an easy induction, the second claim follows by terminal sequence induction, see (Worrell 1999) or Theorem 4.1 of (Pattinson 2004).

In order to obtain an example of two states which are finite step equivalent but not behaviourally equivalent, one therefore needs to consider a functor that is not \(\omega\)-accessible. The following is a standard example.

**Example 3.3.** Let \(TX = \mathcal{P}(X)\) and consider \(C = \omega + 2\), \(\gamma(c) = c\). One shows by induction \(\gamma_n(c) = c \cap n\). Hence \(\omega\) and \(\omega + 1\) are finite step equivalent. If they were behaviourally equivalent, one would obtain \(\gamma_{\omega+1}(\omega) = \gamma_{\omega+1}(\omega + 1)\) which is not the case.

While for states finite step equivalence and \(\omega\)-step equivalence define the same notion of equivalence, for coalgebras \(\omega\)-step equivalence is in general not implied by finite step equivalence.

**Example 3.4.** Let \(TX = \{a, b\} \times X\), \((C, \gamma)\) the final coalgebra with carrier \(\{a, b\}^\omega\) and \((D, \delta)\) the subcoalgebra with carrier \(\{s \cdot a^\omega : s \in \{a, b\}^*\}\). Then \((C, \gamma)\) and \((D, \delta)\) are finite step equivalent, but not \(\omega\)-step equivalent.

In the category \(\text{Coalg}(T)\), morphisms are easily seen to preserve behavioural equivalence. We now introduce the category \(\text{Beh}_\omega(T)\), the morphisms of which are only required to preserve finite step equivalence. Recall that \(\delta_n \circ f = \gamma_n\) if \(\delta_n \circ f = \gamma_n\) for all \(n < \omega\) whenever \((C, \gamma), (D, \delta) \in \text{Coalg}(T)\) and \(f : C \to D\) is any function.

**Definition 3.5** \((\text{Beh}_\omega(T))\). The category \(\text{Beh}_\omega(T)\) has \(T\)-coalgebras as objects. Morphisms \(f : (C, \gamma) \to (D, \delta)\) of \(\text{Beh}_\omega(T)\) are functions \(f : C \to D\) such that \(\delta_n \circ f = \gamma_n\).
Remark 3.6. Clearly, every morphism of coalgebras \( f : (C, \gamma) \to (D, \delta) \in \text{Coalg}(T) \) is also a morphism \( f \in \text{Beh}_\omega(T) \). We hence obtain a functorial inclusion \( \text{Coalg}(T) \to \text{Beh}_\omega(T) \). In order to explain the relationship of \( \text{Beh}_\omega(T) \) to \( \text{Coalg}(T) \) consider the following categories

\[
\begin{array}{c}
\text{c-Beh}(T) \ar@{^{(}->}[r] & \text{Beh}(T) \\
\text{c-Beh}_\omega(T) \ar@{^{(}->}[r] & \text{Beh}_\omega(T)
\end{array}
\]

which all have coalgebras as objects and morphisms as follows. \( f : (C, \gamma) \to (D, \delta) \) is a Beh\((T)\)-morphism iff \( \gamma_n(c) = \delta_n(f(c)) \) for all ordinals \( n \) and all \( c \in C \). The definitions of \( c\text{-Beh}(T) \) and \( c\text{-Beh}_\omega(T) \) follow the same idea, but take colourings into account: \( f : (C, \gamma) \to (D, \delta) \) is a \( c\text{-Beh}_\omega(T) \)-morphism iff \( f \) is a Beh\(_\omega(T \times X)\)-morphism \( (C, \langle \gamma, \nu f \rangle) \to (D, \langle \delta, \nu v \rangle) \) for all \( X \in \text{Set} \) and \( v : D \to X \).

If \( \text{Coalg}(T) \) has cofree coalgebras then \( c\text{-Beh}(T) = \text{Coalg}(T) \). If \( T \) is finitary (i.e. \( \omega \)-accessible) then \( \text{Beh}_\omega(T) = \text{Beh}(T) \) and \( c\text{-Beh}_\omega(T) = c\text{-Beh}(T) \). Whether the converse holds, that is, whether \( c\text{-Beh}_\omega(T) = c\text{-Beh}(T) \) implies that \( T \) is finitary is an open question.

We conclude the section with a couple of simple properties of \( \text{Beh}_\omega(T) \), all of which are also present in \( \text{Coalg}(T) \):

**Proposition 3.7.** Let \( U : \text{Beh}_\omega(T) \to \text{Set} \) be the forgetful functor.

1. \( \text{Beh}_\omega(T) \leftarrow \text{Coalg}(T) \) preserves and reflects coproducts.
2. Injective and surjective morphisms form a factorisation system for \( \text{Beh}_\omega(T) \). In particular, every morphism \( f \in \text{Beh}_\omega(T) \) factors as \( f = m \circ e \) with \( U m \) mono, \( U e \) epi.

**Proof.** The claim on coproducts is immediate. Concerning factorisations, let \( f : (C, \gamma) \to (D, \delta) \) be a morphism in \( \text{Beh}(T) \) and \( C \xrightarrow{i} I \xrightarrow{m} D \) be its epi-mono factorisation in \( \text{Set} \). Choose \( h \) with \( e \circ h = id_I \) and define \( i : I \to TI \) as \( Te \circ \gamma \circ h \). Assuming \( i_n \circ e = \gamma_n \), we verify \( i_{n+1} \circ e = Ti_n \circ e \circ e = \gamma_{n+1} \circ h \circ e = \delta_{n+1} \circ f \circ h \circ e = \delta_{n+1} \circ f = \gamma_{n+1} \), showing that \( e : (C, \gamma) \to (I, i) \) is a morphism, and hence also \( m \). We have seen that factorisations exist in \( \text{Beh}_\omega(T) \). The remaining conditions on a factorisation system (see e.g. (Adámek et al. 1990)) are easy to check. \( \square \)

4. Final and Quasi-Canonical Models

Reasoning about behaviours, the final coalgebra plays a central role because, given the unique coalgebra morphism \( \lambda_C : (C, \gamma) \to (Z, \zeta) \) from a coalgebra \( (C, \gamma) \) into the final coalgebra \( (Z, \zeta) \), for every element \( c \) of \( (\text{the carrier of}) \ (C, \gamma) \), we can consider \( \lambda_C(c) \) as the behaviour of \( c \). Similarly, final objects of \( \text{Beh}_\omega(T) \) (cf. Definition 3.5) consist of the finite behaviours. This section shows that \( \text{Beh}_\omega(T) \) always has a final object which generalises the canonical model construction from Kripke models to coalgebras.
4.1. Final Objects in Behω(T)

A final object of Behω(T) should “realise” all n-step behaviours, n < ω. Accordingly, the carrier of a final object in Behω(T) will be a subset of Tω1.

Recall that, given any coalgebra (C, γ), we write γω for the unique mediating map γω : C → Tω1. That is, all ω-step behaviours appear as some γω(c) in Tω1. On the other hand, it may happen that not every point t ∈ Tω1 can be presented as t = γω(c) by some structure (C, γ) and some c ∈ C. Consider for example the finite powerset functor T = Pω. It has been shown in (Worrell 1999) that for the final T-coalgebra (Z, ζ) the morphism ζω : Z → Tω1 is (injective but) not surjective. Hence we construct the carrier of the coalgebra final in Behω(T) by collecting all t ∈ Tω1 which can be “realised” by some structure, i.e. for which there are (C, γ) ∈ Coalg(T) and c ∈ C such that γω(c) = t.

It then remains to find an appropriate coalgebra structure.

Throughout, we fix the set K of “realisable” elements t ∈ Tω1 which is given by

\[ K = \{ t ∈ Tω1 \mid \exists (C, γ) ∈ \text{Coalg}(T) . \exists c ∈ C . γω(c) = t \} \]

For each k ∈ K, we can now choose (Ck, γk) ∈ Coalg(T) and ck ∈ Ck such that γk(ck) = k. Note that K is a set, which enables us to consider

\[ (C, γ) = \coprod_{k ∈ K} (C_k, γ_k) \]

where the coproduct is taken in Coalg(T). Denoting the coproduct injections by in_k : C_k → C (which, by the construction of coproducts in Coalg(T), are also coproduct injections in the category of sets), we are ready to note:

**Lemma 4.1.** γω ◦ in_k(c) = γω_k(c) for all k ∈ K and c ∈ C_k.

**Proof.** Since γω_k is the unique mediating map into the limiting cone with vertex Tω1, it suffices to prove that γn ◦ in_k(c) = γn_k(c) for all n < ω. For n = 0, this is obvious. For the induction step we calculate γn+1 ◦ in_k(c) = Tγn ◦ γ ◦ in_k(c) = Tγn ◦ Tγn ◦ γ ◦ in_k(c) = Tγn ◦ γ ◦ in_k(c) = γω_k(c).

We obtain the following immediate corollary:

**Corollary 4.2.** For all k ∈ K there exists c ∈ C with γω(c) = k.

In other words, γω factors through K as γω = m ◦ e, m injective, e surjective. Now consider the diagram

\[
\begin{array}{ccc}
TT \xrightarrow{Tm} TK & \xrightarrow{T\gamma} & TC \\
\downarrow{\kappa} & & \uparrow{\gamma} \\
T^ω & \xleftarrow{m} & K \xrightarrow{e} C
\end{array}
\]

where o is any one-sided inverse of e, i.e. e ◦ o = id_K, the existence of which is guaranteed by e being a surjection. We let

\[ K = T\epsilon \circ \gamma \circ o. \]
Note that $\kappa : K \to TK$ makes $K$ into a $T$-coalggebra. Recalling the notation for the limit projections $p_n^\omega : T^n1 \to T^m1$, we obtain

**Lemma 4.3.** For all $n < \omega$, $\kappa_n = p_n^\omega \circ m$, hence $m = \kappa_\omega$.

*Proof.* We proceed by induction on $n$, where the case $n = 0$ is evident. We calculate $\kappa_{n+1} = T\kappa_n \circ \kappa = T(p_n^\omega \circ m) \circ T\gamma_n \circ \gamma \circ o = Tp_n^\omega \circ T\gamma_n \circ \gamma \circ o = T\gamma_n \circ o = p_{n+1}^\omega \circ \gamma \circ o = p_{n+1}^\omega \circ m \circ o \circ o = p_{n+1}^\omega \circ m$ for the induction step, as desired. \qed

The proof of the main theorem of this section is now straightforward.

**Theorem 4.4.** $\text{Beh}_\omega(T)$ has a final object.

*Proof.* We show that $(K, \kappa)$, as constructed above, is final in $\text{Beh}_\omega(T)$. Take any object $(D, \delta) \in \text{Beh}_\omega(T)$. Consider the mapping $\delta_\omega : D \to T^n1$ which is the unique mediating map between the cones $(D, (\delta_n)_{n<\omega})$ and $(T^n1, (p_n^\omega)_{n<\omega})$. By construction, $\delta_\omega$ factors as $\delta_\omega = m \circ h$ where $m : K \to T^n1$ is as above. By Lemma 4.3

$$\delta_\omega = \kappa_\omega \circ h,$$

which implies that $h$ is a $\text{Beh}_\omega(T)$-morphism. $h$ is unique since $\kappa_\omega$ is injective. \qed

Using $!$ to denote the morphisms into the final $\text{Beh}_\omega(T)$-object $(K, \kappa)$, the fact that $\kappa_\omega : K \to T^n1$ is injective gives us

**Corollary 4.5.** Let $(C, \gamma)$, $(D, \delta)$ be $T$-coalgbras and $c \in C$, $d \in D$. Then $c$ and $d$ are finite step equivalent iff $!_C(c) = !_D(d)$.

Final objects in $\text{Beh}_\omega(T)$ are not determined uniquely up to Coalg($T$)-isomorphism. This is due to the fact that not all $\text{Beh}_\omega(T)$-morphisms are also coalgebra morphisms and that, according to objects isomorphic in $\text{Beh}_\omega(T)$ may fail to be isomorphic in Coalg($T$). In case that $p_{n+1}^\omega : T^n1 \to T^{n+1}1$ is surjective\(^\dagger\), we can classify, up to coalgebra isomorphism, the final objects of $\text{Beh}_\omega(T)$ as being given by the right inverses of $p_{n+1}^\omega$.

**Corollary 4.6.** Assume that $p_{n+1}^\omega$ is surjective. An object is final in $\text{Beh}_\omega(T)$ iff it is isomorphic in Coalg($T$) to some $(T^n1, \theta)$ with $p_{n+1}^\omega \circ \theta = id_{T^n1}$.

*Proof.* If: To show that $(T^n1, \theta)$ is final, it suffices to observe that $\theta_n = id_{T^n1}$. This follows from $\theta_n = p_n^\omega$, $n < \omega$, the inductive case being $\theta_{n+1} = T(\theta_n) \circ \theta = T(p_n^\omega \circ \theta = p_{n+1}^\omega \circ p_{n+1}^\omega \circ \theta = p_{n+1}^\omega$.

Only if: Let $(C, \gamma)$ be final in $\text{Beh}_\omega(T)$. Consider a final object $(K, \kappa)$ as constructed in the proof of the theorem. Let $f : (C, \gamma) \to (K, \kappa)$ be the unique morphism. In particular, $f$ is iso and $\kappa_\omega \circ f = \gamma_\omega$. Since $\kappa_\omega$ is injective, $\gamma_\omega$ is as well. Since, by Proposition 1.4(ii), $\gamma_\omega = p_{n+1}^\omega \circ T(\gamma_\omega) \circ \gamma$, $\gamma_\omega$ is also surjective, hence iso. Now define $\theta = T(\gamma_\omega) \circ \gamma \circ \gamma^{-1}$. \qed

\(^\dagger\) Which is the case for all examples in this paper with the exception of $T = \Phi_{\omega}$. A sufficient condition for $p_{n+1}^\omega$ to be surjective is that $T$ weakly preserves limits of $\omega^m$-chains.
We conclude with the useful observation that all \( t \in T^n 1 \), \( n < \omega \), are realised as \( n \)-step behaviours in the final \( \text{Beh}_\omega (T) \)-coalgebra. We first note that every element of an approximant \( T^n 1 \) is realised by a coalgebra.

**Proposition 4.7.** Let \( f \) be any mapping \( 1 \to T 1 \) and \( (C, \gamma) = (T^n 1, T^nf) \). Then \( \gamma_n = id_C \).

As a corollary we obtain that the maps \( \kappa_n \) are surjections:

**Corollary 4.8.** Suppose \((K, \kappa)\) is final in \( \text{Beh}_\omega (T) \) and \( n < \omega \). Then \( \kappa_n \) is a surjection.

**Proof.** Let \((C, \gamma)\) be given as in the above proposition. If \( x \in T^n 1 \), we have \( x = \gamma_n(x) = \kappa_n \circ ! (x) \), where \( ! : (C, \gamma) \to (K, \kappa) \) is the map given by finality. \( \square \)

### 4.2. The Canonical Model

In this section we consider the functor \( M = \mathcal{P} \times \mathcal{P} \text{Prop} \) where \( \text{Prop} \) a countably infinite set.

The **canonical model** (see for example [Blackburn et. al. 2001; Goldblatt 1992]) for the modal logic \( \mathcal{ML} \) is the \( M \)-coalgebra \( (L, \langle \lambda_R, \lambda_V \rangle) \)

\[
\begin{align*}
L & \quad \{ \Phi \subseteq \mathcal{ML} : \Phi \text{ is maximally consistent} \} \\
\lambda_R : L & \to \mathcal{PL} \quad \Phi \mapsto \{ \Psi : \psi \in \Psi \Rightarrow \Diamond \psi \in \Phi \} \\
\lambda_V : L & \to \mathcal{P} \text{Prop} \quad \Phi \mapsto \Phi \cap \text{Prop}
\end{align*}
\]

The canonical model is final in the category \( \text{Th}_{\mathcal{ML}} \) which has \( M \)-coalgebras as objects and whose morphisms \( f : (C, \gamma) \to (D, \delta) \) are functions \( f : C \to D \) such that for all \( c \in C \), \( c \) and \( f(c) \) have the same modal theory.

**Proposition 4.9.** \( \text{Beh}_\omega (M) \cong \text{Th}_{\mathcal{ML}} \).

**Proof.** We have to show that for any coalgebras \( (C, \gamma) \), \( (D, \delta) \) and any function \( f : C \to D \),

\[
\delta_\omega \circ f(c) = \gamma_\omega (c) \iff \text{Th}(c) = \text{Th}(f(c)),
\]

which is equivalent to \( [\forall n < \omega . \delta_n \circ f(c) = \gamma_n (c)] \iff [\forall n < \omega . \forall \varphi \in \mathcal{ML}. \text{rank}(\varphi) = n \Rightarrow (c \models \varphi \iff f(c) \models \varphi)] \) which can be shown using induction on \( n \). \( \square \)

It follows that the canonical model is final in \( \text{Beh}_\omega (M) \). We show now that, conversely, every final object in \( \text{Beh}_\omega (M) \) satisfies the so-called truth-lemma which is the main property of the canonical model.

**Definition 4.10.** A \( M \)-coalgebra \( (L, \lambda) \) is called a **quasi-canonical model** if \( L \) is the set of maximal consistent sets of formulae and

\[
(L, \lambda), \Phi \models \varphi \iff \varphi \in \Phi.
\]

for all \( \Phi \in L \).
The canonical model is quasi-canonical. In fact, it is Property (2) which makes the canonical model useful. In other words, any quasi-canonical model can serve potentially the same purpose as the canonical model. The following theorem characterises the quasi-canonical models as—up to isomorphism of coalgebras—the final coalgebras constructed in the previous subsection. This gives a syntax-free description of the quasi-canonical models.

**Theorem 4.11.** Suppose \((C, \gamma)\) is a \(M\)-coalgebra. Then \((C, \gamma)\) is final in \(\text{Beh}_\omega(M)\) iff \((C, \gamma)\) is \(\text{Coalg}(M)\)-isomorphic to a quasi-canonical model.

*Proof.* First, every quasi-canonical model is easily seen to be final in \(\text{Th}_{\mathcal{MC}}\) and hence, by Proposition 4.9, final in \(\text{Beh}_\omega(M)\). Now suppose \((C, \gamma)\) is final in \(\text{Beh}_\omega(M)\). Since the canonical model \((L, (\lambda_R, \lambda_V))\) is also final in \(\text{Beh}_\omega(M)\), the map \(f : C \rightarrow L, c \mapsto \{\varphi \in \mathcal{MC} | c \models \varphi\}\) is a bijection. Let \(\gamma' = M f^{-1} \circ \gamma \circ f^{-1}\). Then \((C, \gamma') \cong (L, \gamma') \in \text{Coalg}(M)\). It remains to show the truth lemma for \((L, \gamma')\): \((L, \gamma'), \Phi \models \varphi \iff (C, \gamma), f^{-1}(\Phi) \models \varphi \iff \varphi \in f(f^{-1}(\Phi)) \iff \varphi \in \Phi.\)

Since the projection \(p_{\omega+1} : MM^{-1} \rightarrow M^{\omega+1}\) is surjective, Corollary 4.6 shows that the choice of a transition relation on a quasi-canonical model corresponds to the choice of a right inverse of the projection \(p_{\omega+1}\).

**Corollary 4.12.** There is a 1-1 correspondence between the set of quasi-canonical models and the set of right inverses of \(p_{\omega+1}\).

5. Abstract Logics and Their Topologies

In this section, we give an abstract account of the logics we are going to work with in the sequel: logics of finite rank and logics of rank \(\omega\). These logics are the subject of our study in the remainder of this paper, where we prove a compactness theorem and give a characterisation of definable classes of models. Both results rely on (and can be best explained in terms of) the topologies which are defined by the logics under consideration; we give a short account of these topologies.

5.1. Logics of Finite Rank and Logics of Rank \(\omega\)

In Section 3, we introduced a notion of finite step equivalence between elements of coalgebras. This section starts the investigation of logics whose formulae are invariant under finite step equivalence. Since we do not want to commit ourselves to a particular syntax, we assume that a logic \(\mathcal{L}\) for \(T\)-coalgebras already comes with an interpretation function \([\cdot]_C : \mathcal{L} \rightarrow \mathcal{P}(C)\) for every \(T\)-coalgebra \((C, \gamma)\) which maps a formula \(\varphi \in \mathcal{L}\) to the set \([\varphi] \subseteq C\) of states that satisfy \(\varphi\).

**Definition 5.1.** An abstract logic for \(T\)-coalgebras is a pair \((\mathcal{L}, [\cdot])\) where

- \(\mathcal{L}\) is the set of formulae and
- \([\cdot]\) is a family of mappings \([\cdot]_C : \mathcal{L} \rightarrow \mathcal{P}(C)\) indexed by the \(T\)-coalgebras,
such that \( \mathcal{L} \) has (classical) negation and conjunctions which are interpreted as complement and intersection, respectively.

Given an abstract logic \((\mathcal{L}, \cdot)\), \((C, \gamma) \in \text{Coalg}(T)\) and \(c \in C\), we write \(c \models_C \varphi\) if \(c \in \llbracket \varphi \rrbracket_C\) and \(\text{Th}(c) = \{ \varphi \in \mathcal{L} \mid c \models \varphi \}\). Our interest in abstract logics lies in the study the properties that we now introduce.

**Definition 5.2.** Let \(\varphi \in \mathcal{L}\) and \(t \subseteq T^n 1\). We say that \(t\) represents \(\varphi\) iff \(\llbracket \varphi \rrbracket_C = \gamma_n^{-1}(t)\) for all \(T\)-coalgebras \((C, \gamma)\). In this case, \(\varphi\) has rank \(n\). We call a logic \((\mathcal{L}, \cdot)\)

1. of finite rank if every \(\varphi \in \mathcal{L}\) has finite rank.
2. of rank \(\omega\), if every \(\varphi \in \mathcal{L}\) has rank \(\omega\).
3. invariant under finite step equivalence, if \(c \sim_n d\) for all \(n \in \mathbb{N}\) \(\implies\) \(\text{Th}(c) = \text{Th}(d)\).
4. finite step expressive, if for all \(n < \omega\) and all \(t \subseteq T^n 1\) there is \(\varphi \in \mathcal{L}\) such that \(t\) represents \(\varphi\).

Finite step expressive logics play a role similar to the fully expressive logics mentioned in the introduction.

**Example 5.3.** Propositional modal logic is our prime example of a logic of finite rank (Proposition 2.1). A logic of finite rank is also of rank \(\omega\). Linear temporal logic is an example of a logic of rank \(\omega\) which is not of finite rank (Example 2.3). For an endofunctor \(T\), the coalgebraic logic of [Moss 1999] associated with \(T\) is a logic of rank \(\omega\) if \(T\) is \(\omega\)-accessible.

We conclude with two characterisations of logics of rank \(\omega\).

First, in case that the final coalgebra \((Z, \zeta)\) exists, we can represent any logic \(\mathcal{L}\) whose formulae are invariant under behavioural equivalence by \([\cdot]_z : \mathcal{L} \to \mathcal{P}Z\), the \([\cdot]_C\) being determined by \([\cdot]_C = (\lceil \cdot \rceil_C \circ \lceil \cdot \rceil_Z)\) where \(\lceil \cdot \rceil_C : (C, \gamma) \to (Z, \zeta)\) is given by finality in \(\text{Coalg}(T)\).

Similarly, a logic \(\mathcal{L}\) of rank \(\omega\) can be represented by \([\cdot]_K\) where \((K, \kappa)\) is the final object in \(\text{Beh}_\omega(T)\) and \(\lceil \cdot \rceil_C : (C, \gamma) \to (K, \kappa)\) is again given by finality.

Second, logics of rank \(\omega\) are precisely those logics whose formulae are invariant under finite step equivalence:

**Proposition 5.4.** Suppose \(\mathcal{L}\) is an abstract logic and \((K, \kappa)\) is the final object of \(\text{Beh}_\omega(T)\). The following are equivalent:

1. \(\mathcal{L}\) is of rank \(\omega\).
2. \(\llbracket \varphi \rrbracket_C = \lceil \llbracket \varphi \rrbracket_K \rceil_C\) for all \(\varphi \in \mathcal{L}\) and all \(T\)-coalgebras \((C, \gamma)\).
3. \(\mathcal{L}\) is invariant under finite step equivalence.

**Proof.** First suppose that \(\mathcal{L}\) is of rank \(\omega\) and \(\varphi \in \mathcal{L}\). By assumption, there is \(t \subseteq T^n 1\) such that \(\llbracket \varphi \rrbracket_C = \gamma_n^{-1}(t)\) for all \(T\)-coalgebras \((C, \gamma)\). Since \(\lceil \cdot \rceil_C\) is a morphism of \(\text{Beh}_\omega(T)\), we have \(\gamma_\omega = \kappa_\omega \circ \lceil \cdot \rceil_C\). Thus \(\llbracket \varphi \rrbracket_C = \gamma_\omega^{-1}(t) = \lceil \llbracket \varphi \rrbracket_K \rceil_C\).

Next assume \(\llbracket \varphi \rrbracket_C = \lceil \llbracket \varphi \rrbracket_K \rceil_C\) for all \(\varphi \in \mathcal{L}\). Furthermore, let \((C, \gamma), (D, \delta)\) be \(T\)-coalgebras and \((c, d) \in C \times D\) such that \(c \sim_n d\) for all \(n \in \omega\). To show \(\text{Th}(c) = \text{Th}(d)\), pick \(\varphi \in \text{Th}(c)\), that is, \(\lceil \cdot \rceil_C(c) \models \varphi\). From Corollary 4.5 we know \(\llbracket D(d) \rrbracket = \lceil \lceil \cdot \rceil_C(c) \rceil_K\), hence \(\llbracket D(d) \rrbracket = \llbracket \varphi \rrbracket\) and so \(d \models_D \varphi\) by assumption.
Finally assume that \( \mathcal{L} \) is invariant under finite step equivalence and \( \varphi \in \mathcal{L} \). For \( t = [\varphi]_K \subseteq K \subseteq T_\omega^1 \) and \( (C, \gamma) \in \text{Coalg}(T) \), we obtain \( [\varphi]_C = \gamma^{-1}(t) \). □

We conclude that logics of rank \( \omega \) are precisely those logics, whose formulae are invariant under finite step equivalence:

**Corollary 5.5.** A logic is of rank \( \omega \) iff its formulae are invariant under finite step equivalence.

*Proof.* Follows from the above proposition and the observation that, given \( T \)-coalgebras \( (C, \gamma), (D, \delta) \) and \( (c, d) \in C \times D \), we have \( c \sim_\omega d \) iff \( !_C(c) =!_D(d) \), where \( !_C \) and \( !_D \) are the unique morphisms into the final object of \( \text{Beh}_\omega(T) \). □

### 5.2. Topologies on Coalgebras

We now study logics for coalgebras from a topological perspective, where the topology on a model is generated by the set of denotations of logical formulae. We have seen that every formula of rank \( \omega \) can be represented as a subset of the final object in \( \text{Beh}_\omega(T) \). Topology comes into play since one cannot expect that all subsets of the final object can be represented in the logic (since the set of formulae of a logic is in general countable). For introductory material on the relation between logic and topology we refer the reader to (Smyth 1993; Vickers 1998). For the rest of the paper, we assume that \( (\mathcal{L}, [\cdot]) \) is an abstract logic (Definition 5.1). We begin with the definition of the topologies of interest.

**Definition 5.6 (Topologies \( \tau_C \)).** Suppose \( (C, \gamma) \) is a \( T \)-coalgebra. The topology \( \tau_C \) on \( C \) is generated by the basis \( \{ [\varphi]_C \mid \varphi \in \mathcal{L} \} \).

**Remark 5.7.** Suppose \( f : (C, \gamma) \to (D, \delta) \in \text{Beh}_\omega(T) \). If \( \mathcal{L} \) is of rank \( \omega \), the semantics of formulae is stable under \( \text{Beh}_\omega(T) \)-morphisms (Corollary 5.5), hence \( f : (C, \tau_C) \to (D, \tau_D) \) is continuous. Since every morphism of coalgebras qualifies as a \( \text{Beh}_\omega(T) \)-morphism, we have a chain of functors \( \text{Coalg}(T) \to \text{Beh}_\omega(T) \to \text{Top} \), where \text{Top} is the category of topological spaces.

By definition, every formula of a logic of finite rank can be represented as subset \( t \subseteq T_\omega^1 \) for some \( n < \omega \). If the approximants \( T_\omega^1 \) are finite it is natural to assume that all subsets of \( T_\omega^1 \) can be expressed by a formula, that is, that \( \mathcal{L} \) is finite step expressive (cf. Definition 5.2). Since this is not the case in general (see e.g. propositional modal logic over an infinite set of atomic propositions as discussed in Section 2.1), we introduce topologies also on the approximants \( T_\omega^1 \).

**Definition 5.8 (Topologies \( \tau_n, \tau_n^\omega \)).** For \( n < \omega \), the topology \( \tau_n \) on \( T_\omega^1 \) is given by the basis \( \{ t \subseteq T_\omega^1 \mid \exists \varphi \in \mathcal{L} . t \ \text{represents} \ \varphi \} \). If \( (C, \gamma) \) is a \( T \)-coalgebra, the topology \( \tau_n^\omega \) on \( C \) is given by the basis \( \{ \gamma^{-1}(U) \mid U \in \tau_n, n < \omega \} \).

The topology on the approximants would not be worth its salt if it would not turn the connecting morphisms \( p_n^\omega : T_\omega^1 \to T_\omega^1 \) into continuous functions.
Remark 5.9. Suppose $m < n < \omega$ and $t \subseteq T^n1$ represents a formula $\varphi$ of $\mathcal{L}$ (that is, $t$ is a basic open of $(T^n1, \tau_n)$). Then $(p^a_m)^{-1}(t)$ also represents $\varphi$, showing that $p^a_m$ is continuous.

The following easy proposition is useful in that it allows us to compute the topologies $\tau_C$ via the topologies on the approximants $T^n1$.

Proposition 5.10. Let $\mathcal{L}$ be a logic of finite rank and $(C, \gamma)$ a coalgebra. Then the topologies $\tau^C$ and $\tau_C$ coincide.

The converse of the proposition only holds in compact spaces. Before we turn to compactness issues, we discuss an important special case:

Definition 5.11 (Cantor space topology). In case that $\mathcal{L}$ is finite step expressive, that is, in case the topologies $\tau_n$ are discrete, we call $\tau^C_C$ the Cantor space topology.

The terminology is motivated by the following example.

Example 5.12. Suppose $TX = 2 \times X$, where $2 = \{0, 1\}$. Consider the (final) $T$-coalgebra $(C, \gamma)$ with $C = 2^\omega = \{f : \omega \to 2\}$ and $\gamma(f) = (f(0), \lambda n . f(n + 1))$. Then $(C, \tau_C)$ is homeomorphic to the Cantor discontinuum $\mathbb{C}$ (also known as middle-third set, see e.g. (Jelley 1995)) via the mapping $2^\omega \to \mathbb{C}$, $f \mapsto \sum_{i=0}^{\infty} \frac{f(i) - \gamma_0}{2^i}$.

Remark 5.13. Let $(C, \gamma) \in \text{Coalg}(T)$ and let, for $c_0, c_1 \in C$, $d_C(c_0, c_1) = \inf\{2^{-n} : \forall k < n . \gamma_k(c_0) = \gamma_k(c_1)\}$. Then $d_C$ is a pseudo-ultrametric on $C$, and $d_C$ is a ultrametric if $\gamma_\omega : C \to T^\omega 1$ is injective. The Cantor space topology $\tau_C$ coincides with the topology induced by $d_C$, as studied in (Barr 1993; Worrell 2000).

In the remainder of the section we relate topological and logical notions. All of the results below are consequences of the observation that

— the subsets expressible by single formulae form a basis
— this basis is closed under complements (and finite unions)

where the second point is due to the requirement that the logics are closed under boolean operators (Definition 5.1).

We shall often require our topologies to be compact and Hausdorff. The relationship of these properties to logical issues becomes apparent in the context of final coalgebras in $\text{Beh}_\omega(T)$.

Proposition 5.14. Suppose $(K, \kappa)$ is final in $\text{Beh}_\omega(T)$.

1. $K$ is Hausdorff iff for all distinct $k_1, k_2 \in K$ there is $\varphi \in \mathcal{L}$ such that $k_1 \models \kappa \varphi$ and $k_2 \not\models \kappa \varphi$.
2. $K$ is compact iff for all $\Phi \subseteq \mathcal{L}$ with $\Phi \models \kappa \varphi$ there is a finite subset $\Phi' \subseteq \Phi$ with $\Phi' \models \varphi$.

\footnote{A set is \textit{compact} if any open cover has a finite subcover. This is sometimes called quasi-compact. A space $(X, \tau)$ is \textit{Hausdorff} iff $\forall x, y \in X . x \neq y \implies \exists U, V \in \tau . x \in U \land y \in V \land U \cap V = \emptyset$.}
Logically speaking, \( K \) is Hausdorff iff \( \mathcal{L} \) is expressive in the sense that every pair of different states can be separated by a formula. Compactness says that if \( \varphi \) is a consequence of a set \( \Phi \) of formulae, there is a finite subset \( \Phi' \subseteq \Phi \) such that \( \Phi' \) already forces the validity of \( \varphi \). For finitary logics with a sound and complete axiomatisation this is always the case, since a proof of \( \varphi \) from \( \Phi \) can only use finitely many premises. Since we study logics without making any commitment to a particular syntax, this property is not guaranteed and we have to require it for a number of results in the sequel.

The following are easy consequences of the definition of the topologies as generated by the semantics of modal formulae, where we call a \( T \)-coalgebra \( (C, \gamma) \) logically compact, if every set \( \Phi \) of formulae that is finitely satisfiable in \( (C, \gamma) \) (that is, for every finite subset \( \Phi' \subseteq \Phi \) there exists \( c \in C \) such that \( c \models \Phi' \) is satisfiable in \( (C, \gamma) \) (i.e. there exists \( c \in C \) such that \( c \models \Phi \)).

**Proposition 5.15.** Let \( (C, \gamma) \in \text{Coalg}(T) \).

1. A subset of \( C \) is definable by a set of formulae iff it is closed w.r.t. \( \tau_C \).
2. If \( (C, \tau_C) \) is compact, then any clopen is expressible by a single formula.
3. \( (C, \gamma) \) is logically compact iff \( (C, \tau_C) \) is topologically compact.

The proof is standard and therefore omitted. From a logical point of view, compactness corresponds to finiteness of proofs and is therefore not an issue for finitary logics that have a sound and complete axiomatisation. However, there are models that are not compact:

**Example 5.16.** Let \( TX = D \times X \) and consider the final coalgebra \( (Z, \zeta) \) given by \( Z = D^\omega \).

1. \( (Z, \zeta) \) is compact in the Cantor space topology iff \( D \) is finite.
2. Suppose \( D = \{a, b\} \). Then examples of non-compact coalgebras are given by the carriers \( Z \setminus \{b^\omega\} \) and \( \{s \cdot a^\omega : s \in \{a, b\}^*\} \) (and inheriting the structure from \( \zeta \)).

**Example 5.17.** Let \( TX = \{a, b\} \times X + 1 \) and consider the final coalgebra \( (Z, \zeta) \) with \( Z = \{a, b\}^* \cup \{a, b\}^\omega \). Then \( Z \) is compact in the Cantor space topology (since the limit of compact Hausdorff spaces is compact Hausdorff, see (Engelking 1989), 3.2.13) and \( \{a, b\}^* \) is not compact. The topology on \( Z \) is as follows. A subset of \( Z \) is open iff it is a subset of \( \{a, b\}^* \) or of the form \( V \cdot \{a, b\}^* + \{a, b\}^\omega \) for some \( V \subseteq \{a, b\}^* \). In particular, every open cover of \( \{a, b\}^\omega \) also covers \( \{a, b\}^* \).

Another example where the final coalgebra is not compact is obtained for \( TX = \mathcal{P}_\omega(X) \) by applying Proposition 5.15 (3).

**Example 5.18.** For finitely branching Kripke structures, i.e. \( T = \mathcal{P}_\omega \), it is not difficult to write down formulae \( \varphi_n \) that force any point satisfying \( \varphi_n \) to have at least \( n \) successors. The set \( \Phi = \{\varphi_n \mid n < \omega\} \) is then finitely satisfiable, but not satisfiable by a \( \mathcal{P}_\omega \)-coalgebra.

6. **Compactness for Logics of Rank \( \omega \)**

It is well known that (standard) model logic is compact. Generalising to coalgebras compactness may fail, for example in the case of image-finite Kripke models (Example 5.18).
Hence we are drawn to investigate sufficient and necessary conditions for the compactness theorem to hold.

Extending the terminology we have introduced in Section 5.2 on the level of models, we call a set $\Phi \subseteq \mathcal{L}$ is satisfiable, if there exists a $T$-coalgebra $(C, \gamma)$ such that $\Phi$ is satisfiable in $(C, \gamma)$. We call $\Phi$ finitely satisfiable, if every finite subset of $\Phi$ is satisfiable. Finally, a logic $\mathcal{L}$ is compact, if every finitely satisfiable set of formulae is satisfiable. Using this terminology, we are in the position to present the first version of the compactness theorem.

**Theorem 6.1.** Suppose $\mathcal{L}$ is of rank $\omega$. Then $\mathcal{L}$ is compact iff $\text{Beh}_\omega(T)$ has a compact final object.

**Proof.** Only if: By Theorem 4.4 there exists a final object $(K, \kappa) \in \text{Beh}_\omega(T)$. We show that $(K, \kappa)$ is logically compact, from which the result then follows by Proposition 5.15. So suppose $\Phi \subseteq \mathcal{L}$ is finitely satisfiable in $(K, \kappa)$. By compactness, $\Phi$ is satisfiable. Hence there is $(C, \gamma)$ and $c \in C$ such that $c \models C \Phi$. Since $(K, \kappa)$ is final in $\text{Beh}_\omega(T)$, there is a mapping $u : (C, \gamma) \rightarrow (K, \kappa) \in \text{Beh}_\omega(T)$. By definition of morphisms in $\text{Beh}_\omega(T)$, we obtain $u(c) \models K \Phi$. Hence $\Phi$ is satisfiable in $(K, \kappa)$.

if: Let $(K, \kappa)$ be compact and final in $\text{Beh}_\omega(T)$ and suppose $\Phi \subseteq \mathcal{L}$ is finitely satisfiable. Then $\Phi$ by finitely and by definition of morphisms in $\text{Beh}_\omega(T) - \Phi$ is finitely satisfiable in $(K, \kappa)$, hence satisfiable in $(K, \kappa)$ by compactness and Proposition 5.15. □

We now proceed to characterise those endofunctors $T$ for which $\text{Beh}_\omega(T)$ has a compact final object. Concerning the logics, we need to impose the following

**Condition 6.2.** The topologies $\tau_n$ are compact and Hausdorff.

Logically speaking, this condition expresses that, for a given logic $\mathcal{L}$, the induced sublogics $\mathcal{L}_n$ of formulae of finite rank are compact and expressive. The reader is referred to Section 5.2 for a brief discussion of compactness and the Hausdorff property in the context of logics.

It will turn out that $\text{Beh}_\omega(T)$ has a compact final object iff $T$ weakly preserves the limit of its final sequence up to $\omega$. More precisely, we say that $T$ weakly preserves the limit of the sequence $(T^\omega n)_{n \in \omega}$, if the cone $(TT^\omega 1, (T p_n^\omega)_{n \in \omega})$ is weakly limiting. We first show that the carrier of a compact final object in $\text{Beh}_\omega(T)$ is isomorphic to $T^\omega 1$. This is the crucial step in our proof.

**Lemma 6.3.** Assume Condition 6.2. If $(K, \kappa)$ is compact and final in $\text{Beh}_\omega(T)$, then $\kappa_\omega : K \rightarrow T^\omega 1$ is iso.

**Proof.** It follows from the construction of $(K, \kappa)$ that $\kappa_\omega$—called $m$ in Diagram (1)—is injective. To see that $\kappa_\omega$ is surjective, consider $t \in T^\omega 1$. The elements of the set $S = \{\kappa_n^{-1}(\{p_n^\omega(t)\}) \mid n \in \omega\}$ are closed (since in a Hausdorff space one-element sets are closed) and non-empty (follows from Corollary 4.8). It follows from $\kappa_n^{-1}(\{p_n^\omega(t)\}) \cap$

\footnote{A weak limit is defined like a limit but the mediating morphism need not be unique.}
\( \kappa_n^{-1}(\{p_{m,n}^n(t)\}) = \kappa_{\min(n,m)}^{-1}(\{p_{\min(n,m)}^n(t)\}) \) that \( S \) has the finite intersection property. By compactness, there is \( k \in \bigcap S \). Since \( \kappa_n(k) = p_n^n(t) \) for all \( n \in \omega \), it follows \( \kappa(k) = t \). \( \square \)

We are now able to prove our second compactness theorem showing that, under suitable hypotheses, a logic of finite rank is compact iff \( T \) weakly preserves the limit of \( (T^n1)_{n<\omega} \).

**Theorem 6.4.** Let \( L \) be a logic of finite rank satisfying Condition 6.2. The final object of \( \text{Beh}_\omega(T) \) is compact iff \( T \) weakly preserves the limit of \( (T^n1)_{n<\omega} \).

**Proof.** Observe that \( T \) weakly preserves the limit of \( (T^n1)_{n<\omega} \) iff \( p_{\omega+1}^n \) has a one-sided inverse \( i, p_{\omega+1}^n \circ i = id_{T^n1} \).

\[ \Rightarrow: \] Let \( (K, \kappa) \) be final and compact in \( \text{Beh}_\omega(T) \). Due to the lemma above, we can define \( i = T_{K, \kappa} \circ \kappa^{-1} \). It remains to check that indeed \( p_{\omega+1}^n \circ i = p_{\omega+1}^n \circ T_{K, \kappa} \circ \kappa^{-1} = \kappa_{\omega} \circ \kappa^{-1} = id_{T^n1} \).

\[ \Leftarrow: \] Let \( p_{\omega+1}^n \circ i = id_{T^n1} \). It was shown in Corollary 4.6 that \( (T^n1, i) \) is final in \( \text{Beh}_\omega(T) \). It is compact since \( T^n1 \) is the limit of compact Hausdorff spaces and the induced topology on a limit of compact Hausdorff spaces is compact Hausdorff (see (Engelking 1989), 3.2.13).

**Remark 6.5.** An inspection of the proof shows that \( \Rightarrow \) also holds for logics of rank \( \omega \). Moreover, for \( \Rightarrow \), we can weaken Condition 6.2 and only require that elements of \( T^n1, n < \omega \), are closed w.r.t. \( \tau_n \). On the other hand, \( \Leftarrow \) does not hold for logics of rank \( \omega \) as can be seen in the example of \( \text{LTL} \) (Section 2.2). Indeed, \( \{\Box^n p \mid n < \omega\} \cup \{\neg \Box p\} \) is finitely satisfiable but not satisfiable.

For the Cantor space topology, we have the following:

**Corollary 6.6.** Let \( T \) map finite sets to finite sets. The final object of \( \text{Beh}_\omega(T) \) is compact in the Cantor space topology iff \( T \) weakly preserves the limit of \( (T^n1)_{n<\omega} \).

Note that in this case Condition 6.2 is automatically satisfied.

### 7. Definability for Logics of Rank \( \omega \)

In this section we prove a characterisation result for classes of coalgebras definable by logics of rank \( \omega \). The main idea is again to replace \( \text{Coalg}(T) \) by \( \text{Beh}_\omega(T) \) and to reuse well-known techniques\(^*\). We begin by relating morphisms of \( \text{Beh}_\omega(T) \) and \( \text{Coalg}(T) \)-morphisms.

**Proposition 7.1.** For any injective \( \text{Beh}_\omega(T) \)-morphism \( m : (C, \gamma) \to (D, \delta) \) there is \( \delta' \) such that \( m : (C, \gamma) \to (D, \delta') \) is a \( \text{Coalg}(T) \)-morphism and \( id_D : (D, \delta') \to (D, \delta) \) is a \( \text{Beh}_\omega(T) \)-morphism.

\(^*\) See e.g. (Adámek et. al. 1990), Chapter 16 for a textbook presentation and (Kurz 2000), Chapter 2 for applications to modal logic.
Proof. Let $L$ be the image of $m, m_0 : C \to L$ the induced mapping, and $R = D \setminus L$. Define $\lambda : L \to TD$ as $Tm \circ \gamma \circ m_0^{-1}$ and $\delta' : D \cong L + R \to TD$ as $[\lambda, \delta \circ \text{imr}]$. Then $m$ is a $\text{Coalg}(T)$-morphism since $\delta' \circ m = \lambda \circ m_0 = Tm \circ \gamma$. To see that $id_D$ is a $\text{Beh}_n(T)$-morphism assume $\delta'_n = \delta_n$ and consider the following two cases: for $d \in L$, $\delta'_{n+1}(d) = \gamma_{n+1}(m^{-1}(d)) = \delta_{n+1}(m(m^{-1}(d))) = \delta_{n+1}(d)$; for $d \in R$, $\delta'_{n+1}(d) = T\delta'_n \circ \delta'(d) = T\delta_n \circ \delta(d) = \delta_{n+1}(d)$.

In addition to the classical closure operators we need a further one accounting for the restricted expressiveness of logics of rank $\omega$.

**Definition 7.2.** Let $\mathcal{L}$ be a logic and $(K, \kappa)$ the final object in $\text{Beh}_n(T)$. Define a relation $\sim^\omega_{\mathcal{L}}$ on coalgebras via

$$(C, \gamma) \sim^\omega_{\mathcal{L}} (D, \delta) \iff \text{cl}(!_C(C)) = \text{cl}(!_D(D))$$

where $!$ denotes the morphisms given by finality of $(K, \kappa)$ and $\text{cl}$ denotes the topological closure w.r.t. $(K, \tau_K)$ (Definition 5.6).

The theorem below parallels the definability theorem for infinitary modal logics, but adds $\sim^\omega_{\mathcal{L}}$ to the closure operators.

**Theorem 7.3.** Let $\mathcal{L}$ be a logic of rank $\omega$. A class $B$ of $T$-coalgebras is definable by a set of formulae iff $B$ is closed under coproducts, subcoalgebras, and $\sim^\omega_{\mathcal{L}}$.

*Proof:* Since $\mathcal{L}$ is of rank $\omega$, Proposition 5.4 shows that $\mathcal{L}$ can be represented by $[\cdot]_K : \mathcal{L} \to \mathcal{P}K$, where $(K, \kappa)$ denotes the final object of $\text{Beh}_n(T)$. Recall that $(C, \gamma) \models \varphi \iff !_C(C) \subseteq [\varphi]$ where $!_C$ is the morphism given by finality. From this observation 'only if' follows easily (for closure under $\sim^\omega_{\mathcal{L}}$ recall Proposition 5.15).

For 'if', note first that the assumed closure conditions imply: $(C, \gamma) \to (D, \delta)$ is a surjective $\text{Beh}_n(T)$-morphism only if $(C, \gamma) \in B \Rightarrow (D, \delta) \in B$; and $(C, \gamma) \to (D, \delta)$ is a $\text{Beh}_n(T)$-morphism only if $(D, \delta) \in B \Rightarrow (C, \gamma) \in B$ (use Proposition 7.1); and for a class $\{f_i : (C, \gamma_i) \to (D, \delta) \mid i \in I\}$ of $\text{Beh}_n(T)$-morphisms with $(C, \gamma_i) \in B$, the union of the images of the $f_i$ carries a coalgebraic structure and is in $B$ (use Proposition 3.7). Let $(S, \sigma)$ be the coalgebra given by the union of the images of all $!_D : (D, \delta) \to (K, \kappa)$, $(D, \delta) \in B$. By Proposition 5.15, $\text{cl}$ is expressible in $\mathcal{L}$ by a set of formulae $\Phi$. We show that $B = \text{Mod}(\Phi)$. For $(D, \delta) \in B$ we have, by definition of $S$, $(D, \delta) \models \Phi$. To show $B \supseteq \text{Mod}(\Phi)$, define $(S, \sigma)$ as the largest subcoalgebra of $\text{cl}(S)$. Since $S \subseteq \text{cl}(S)$, it follows $\text{cl}(S) = \text{cl}(\bar{S})$, hence $(S, \sigma) \sim^\omega_{\mathcal{L}} (S, \sigma)$. Since $B$ is closed under images and coproducts, $B$ is also closed under unions, hence $(S, \sigma) \in B$, hence $(S, \sigma) \in B$. Now assume $(C, \gamma) \models \Phi$, that is, $!_C(C) \subseteq \text{cl}(S)$ and hence $!C(C) \subseteq \bar{S}$, i.e. there is a morphism $(C, \gamma) \to (S, \sigma)$. Since $B$ is closed under domains of morphisms, $(C, \gamma) \in B$.

For the Cantor space, we obtain:

**Corollary 7.4.** Let $\mathcal{L}$ be a finite step expressively finite rank $\omega$. A class $B$ of $T$-coalgebras is definable by a set of formulae if $B$ is closed under coproducts, subcoalgebras, and $\sim^\omega_{\mathcal{L}}$. 

8. Conclusions and Related Work

We have studied definability and compactness for finitary coalgebraic modal logic. The main instrument through which finitary logics have been studied is the modal sequence and the shift from the category Coalg\( (T) \) to the category Beh\( \omega \)(\( T) \).

In this category, points (or states) can be distinguished if their finite behaviour differs. Also, Beh\( \omega \)(\( T) \) provides the right framework in which the construction of canonical models can be generalised to a coalgebraic setting. The main handle that allows us to formalise the finitary character of the logics considered is to identify finitary predicates with subsets of \( T^n \lceil_1 \), where \( n \) is a finite ordinal. The idea of interpreting formulae on the elements \( T^n \lceil_1 \) of the terminal sequence was already used in (Pattinson 2001). The same idea (without the restriction to finite ordinals) also prevails in (Moss 1999). There, formulae are constructed using infinitary conjunctions (which do not change the degree of the formulae) and the application of the signature functor \( T \) (increasing the degree of the constructed formulae by 1).

The signature functors (and hence the logics) that have been discussed in the present paper are all one-sorted. The passage to multi-sorted signatures, i.e. endofunctors \( \text{Set}_n^\omega \rightarrow \text{Set}_n^\omega \) is standard and allows us to include the logics discussed in (Rößler 2000a; Jacobs 2001a) which also rely on (syntactically defined) predicate liftings. Since the endofunctors discussed in loc. cit. are all \( \omega \)-accessible, final coalgebras and canonical models coincide for these logics (which is also reflected by the fact that they are strong enough to characterise behavioural equivalence).

A coalgebraic representation of the Cantor discontinuum has also been given in (Pavlovic and Pratt 2000) in the category of posets. The cantor space topology discussed in the present paper arises in a different way: We start with a final coalgebra on the category of sets which is then equipped with a natural topology.
