

Category Theory Session 4: Questions

Dirk Pattinson

March 29, 2022

- Let \mathcal{C} be a category with finite products. Call an object B in a category *exponentiable*, if the exponential C^B exists in the category, for all objects $B \in \mathcal{C}$.

We have seen tht this is equivalent to the existence of a functor $E : \mathcal{C} \rightarrow \mathcal{C}$ and a family of maps $\epsilon_C : E(C) \times B \rightarrow C$ with the following universal property:

For all $f : A \times B \rightarrow C$ there exists a unique $\tilde{f} : A \rightarrow E(C)$ such that the diagram

$$\begin{array}{ccc} A \times B & & \\ \tilde{f} \times 1_B \downarrow & \searrow f & \\ E(C) \times B & \xrightarrow{\epsilon_B} & C \end{array}$$

commutes.

Show that an object B is exponentiable if and only if there is a functor $E : \mathcal{C} \rightarrow \mathcal{C}$ and a family of maps $\eta_{AB} : A \rightarrow E(A \times B)$ with the following universal property:

For all $f : A \times B \rightarrow C$ there exists a unique $\hat{f} : A \rightarrow E(C)$ such that

$$\begin{array}{ccc} A & & \\ \eta_{AB} \downarrow & \searrow f & \\ E(A \times B) & \xrightarrow{E(\hat{f})} & E(C) \end{array}$$

commutes.

- It is easy to see that the category of metric spaces (and continuous functions) has binary products. Is it cartesian closed?
- Show that in a cartesian closed category, $A^{(B^C)} \cong (A^B)^C$.

4. Let \mathcal{O} be the lattice of open sets of a topological space, ordered by inclusion. Show that \mathcal{O} , viewed as a category, is cartesian closed, and has finite coproducts. That is, show that \mathcal{O} carries the structure of a Heyting algebra.
