Multiple View Geometry

Richard Hartley and Andrew Zisserman

CVPR June 1999
Part I: Single and Two View Geometry

The main points covered in this part are:

- A perspective (central) projection camera is represented by a $3 \times 4$ matrix.

- The most general perspective transformation transformation between two planes (a world plane and the image plane, or two image planes induced by a world plane) is a plane projective transformation. This can be computed from the correspondence of four (or more) points.

- The epipolar geometry between two views is represented by the fundamental matrix. This can be computed from the correspondence of seven (or more) points.
Perspective projection

\[
\lambda \begin{pmatrix} x \\ y \\ f \end{pmatrix} = \begin{pmatrix} X \\ Y \\ Z \end{pmatrix}
\]

where \( \lambda = \frac{Z}{f} \).

This can be written as a linear mapping between homogeneous coordinates (the equation is only up to a scale factor):

\[
\begin{pmatrix} x \\ y \\ f \end{pmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \end{bmatrix} \begin{pmatrix} X \\ Y \\ Z \\ 1 \end{pmatrix}
\]

where a \( 3 \times 4 \) projection matrix represents a map from 3D to 2D.
**Image Coordinate System**

**Internal camera parameters**

\[
\begin{align*}
k_x \ x_{\text{cam}} &= x - x_0 \\
k_y \ y_{\text{cam}} &= y - y_0
\end{align*}
\]

where the units of \( k_x, k_y \) are [pixels/length].

\[
\mathbf{x} = \begin{pmatrix} x \\ y \\ 1 \end{pmatrix} = \frac{1}{f} \begin{bmatrix} \alpha_x & x_0 \\ \alpha_y & y_0 \\ f \end{bmatrix} \begin{pmatrix} x_{\text{cam}} \\ y_{\text{cam}} \\ f \end{pmatrix} = \mathbf{K} \begin{pmatrix} x_{\text{cam}} \\ y_{\text{cam}} \end{pmatrix}
\]

where \( \alpha_x = f k_x, \ \alpha_y = f k_y \).
Camera Calibration Matrix

K is a $3 \times 3$ upper triangular matrix, called the camera calibration matrix:

$$K = \begin{bmatrix}
\alpha_x & x_0 \\
\alpha_y & y_0 \\
1 & 1
\end{bmatrix}$$

- There are four parameters:
  1. The scaling in the image $x$ and $y$ directions, $\alpha_x$ and $\alpha_y$.
  2. The principal point $(x_0, y_0)$, which is the point where the optic axis intersects the image plane.
- The aspect ratio is $\alpha_y/\alpha_x$. 
World Coordinate System

External camera parameters

\[
\begin{pmatrix}
X_{\text{cam}} \\
Y_{\text{cam}} \\
Z_{\text{cam}} \\
1
\end{pmatrix} = \begin{bmatrix}
\mathbf{R} & \mathbf{t} \\
\mathbf{0}^T & 1
\end{bmatrix}
\begin{pmatrix}
X \\
Y \\
Z \\
1
\end{pmatrix}
\]

Euclidean transformation between world and camera coordinates

- \( \mathbf{R} \) is a \( 3 \times 3 \) rotation matrix
- \( \mathbf{t} \) is a \( 3 \times 1 \) translation vector
Concatenating the three matrices,

\[
x = \begin{pmatrix} x \\ y \\ 1 \end{pmatrix} = K \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \end{bmatrix} \begin{bmatrix} R \\ t \end{bmatrix} \begin{pmatrix} X \\ Y \\ Z \\ 1 \end{pmatrix} = K [R \mid t] X
\]

which defines the $3 \times 4$ projection matrix from Euclidean 3-space to an image as

\[
x = P X \quad P = K [R \mid t] = KR[I \mid R^\top t]
\]

Note, the camera centre is at $(X, Y, Z)^\top = -R^\top t$.

In the following it is often only the $3 \times 4$ form of $P$ that is important, rather than its decomposition.
A Projective Camera

The camera model for perspective projection is a linear map between homogeneous point coordinates

\[
\begin{pmatrix}
x \\
y \\
1
\end{pmatrix}
= \begin{pmatrix}
P
\end{pmatrix}_{(3 \times 4)}
\begin{pmatrix}
X \\
Y \\
Z \\
1
\end{pmatrix}
\]

- The camera centre is the null-vector of \( P \)
e.g. if \( P = [I|0] \) then the centre is \( X = (0, 0, 0, 1)^\top \).
- \( P \) has 11 degrees of freedom (essential parameters).
- \( P \) has rank 3.
What does calibration give?

- $K$ provides the transformation between an image point and a ray in Euclidean 3-space.
- Once $K$ is known the camera is termed calibrated.
- A calibrated camera is a direction sensor, able to measure the direction of rays — like a 2D protractor.

\[
\begin{align*}
\mathbf{x} &= \begin{pmatrix} x \\ y \\ 1 \end{pmatrix} = \begin{bmatrix} \alpha_x & x_0 \\ \alpha_y & y_0 \\ 0 & 1 \end{bmatrix} \begin{pmatrix} X_{\text{cam}} \\ Y_{\text{cam}} \\ Z_{\text{cam}} \end{pmatrix} = K\mathbf{d}
\end{align*}
\]
Angle between rays

\[ \cos \theta = \frac{d_1 \cdot d_2}{(d_1 \cdot d_1)^{\frac{1}{2}}(d_2 \cdot d_2)^{\frac{1}{2}}} \]

\[ \cos \theta = \frac{d_1^T d_2}{(d_1^T d_1)^{\frac{1}{2}}(d_2^T d_2)^{\frac{1}{2}}} = \frac{x_1^T (K^{-T} K^{-1}) x_2}{(x_1^T (K^{-T} K^{-1}) x_1)^{\frac{1}{2}}(x_2^T (K^{-T} K^{-1}) x_2)^{\frac{1}{2}}} \]

\[ = \frac{x_1^T \omega x_2}{(x_1^T \omega x_1)^{\frac{1}{2}}(x_2^T \omega x_2)^{\frac{1}{2}}} \]

where \( \omega = (KK^T)^{-1} \).
Problem Statement:

Given \( n \) correspondences \( x_i \leftrightarrow X_i \), where \( X_i \) is a scene point and \( x_i \) its image:

Compute

\[
P = K [R | t]
\]

such that \( x_i = P X_i \).

The algorithm for camera calibration has two parts:

(i) Compute the matrix \( P \) from a set of point correspondences.

(ii) Decompose \( P \) into \( K, R \) and \( t \) via the QR decomposition.
Algorithm step 1: Compute the matrix $\mathbf{P}$

$x_i = \mathbf{P} \mathbf{X}_i$.

Each correspondence generates two equations

$$x_i = \frac{p_{11}X_i + p_{12}Y_i + p_{13}Z_i + p_{14}}{p_{31}X_i + p_{32}Y_i + p_{33}Z_i + p_{34}} \quad y_i = \frac{p_{21}X_i + p_{22}Y_i + p_{23}Z_i + p_{24}}{p_{31}X_i + p_{32}Y_i + p_{33}Z_i + p_{34}}$$

Multiplying out gives equations linear in the matrix elements of $\mathbf{P}$

$$x_i(p_{31}X_i + p_{32}Y_i + p_{33}Z_i + p_{34}) = p_{11}X_i + p_{12}Y_i + p_{13}Z_i + p_{14}$$
$$y_i(p_{31}X_i + p_{32}Y_i + p_{33}Z_i + p_{34}) = p_{21}X_i + p_{22}Y_i + p_{23}Z_i + p_{24}$$

These equations can be rearranged as

$$\begin{pmatrix} x & y & z & 1 & 0 & 0 & 0 & 0 & -x & -x & -y & -z & -x \\ 0 & 0 & 0 & 0 & x & y & z & 1 & -y & -y & -x & -y & -z \end{pmatrix} \mathbf{p} = \mathbf{0}$$

with $\mathbf{p} = (p_{11}, p_{12}, p_{13}, p_{14}, p_{21}, p_{22}, p_{23}, p_{24}, p_{31}, p_{32}, p_{33}, p_{34})^\top$ a 12-vector.
Solving for $P$

(i) Concatenate the equations from $(n \geq 6)$ correspondences to generate $2n$ simultaneous equations, which can be written: $Ap = 0$, where $A$ is a $2n \times 12$ matrix.

(ii) In general this will not have an exact solution, but a (linear) solution which minimises $|Ap|$, subject to $|p| = 1$ is obtained from the eigenvector with least eigenvalue of $A^TA$. Or equivalently from the vector corresponding to the smallest singular value of the SVD of $A$.

(iii) This linear solution is then used as the starting point for a non-linear minimisation of the difference between the measured and projected point:

$$\min_P \sum_i ((x_i, y_i) - P(X_i, Y_i, Z_i, 1))^2$$
Determine accurate corner positions by

(i) Extract and link edges using Canny edge operator.
(ii) Fit lines to edges using orthogonal regression.
(iii) Intersect lines to obtain corners to sub-pixel accuracy.

The final error between measured and projected points is typically less than 0.02 pixels.
Algorithm step 2: Decompose $P$ into $K$, $R$ and $t$

The first $3 \times 3$ submatrix, $M$, of $P$ is the product ($M = KR$) of an upper triangular and rotation matrix.

(i) Factor $M$ into $KR$ using the QR matrix decomposition. This determines $K$ and $R$.

(ii) Then

$$t = K^{-1}(p_{14}, p_{24}, p_{34})^\top$$

Note, this produces a matrix with an extra skew parameter $s$

$$K = \begin{bmatrix}
\alpha_x & s & x_0 \\
0 & \alpha_y & y_0 \\
0 & 0 & 1
\end{bmatrix}$$

with $s = \tan \theta$, and $\theta$ the angle between the image axes.
Weak Perspective

Track back, whilst zooming to keep image size fixed

The imaging rays become parallel, and the result is:

\[ P = K \begin{bmatrix} r_{11} & r_{12} & r_{13} & * \\ r_{21} & r_{22} & r_{23} & * \\ 0 & 0 & 0 & * \end{bmatrix} \]

A generalization is the *affine camera*
The Affine Camera

\[ P = \begin{bmatrix} m_{11} & m_{12} & m_{13} & t_1 \\ m_{21} & m_{22} & m_{23} & t_2 \\ 0 & 0 & 0 & 1 \end{bmatrix} \]

The matrix \( M_{2 \times 3} \) has rank two.

Projection under an affine camera is a linear mapping on non-homogeneous coordinates composed with a translation:

\[
\begin{pmatrix} x \\ y \end{pmatrix} = \begin{bmatrix} m_{11} & m_{12} & m_{13} \\ m_{21} & m_{22} & m_{23} \end{bmatrix} \begin{pmatrix} X \\ Y \\ Z \end{pmatrix} + \begin{pmatrix} t_1 \\ t_2 \end{pmatrix}
\]

- The point \((t_1, t_2)^\top\) is the image of the world origin.
- The centre of the affine camera is at infinity.
- An affine camera has 8 degrees of freedom.
- It models weak-perspective and para-perspective.
Choose the world coordinate system such that the plane of the points has zero $Z$ coordinate. Then the $3 \times 4$ matrix $P$ reduces to

$$
\begin{pmatrix}
  x_1 \\
  x_2 \\
  x_3 \\
\end{pmatrix} = 
\begin{bmatrix}
  p_{11} & p_{12} & p_{13} & p_{14} \\
  p_{21} & p_{22} & p_{23} & p_{24} \\
  p_{31} & p_{32} & p_{33} & p_{34} \\
\end{bmatrix}
\begin{pmatrix}
  X \\
  Y \\
  0 \\
\end{pmatrix} = 
\begin{bmatrix}
  p_{11} & p_{12} & p_{14} \\
  p_{21} & p_{22} & p_{24} \\
  p_{31} & p_{32} & p_{34} \\
\end{bmatrix}
\begin{pmatrix}
  X \\
  Y \\
  1 \\
\end{pmatrix}
$$

which is a $3 \times 3$ matrix representing a general plane to plane projective transformation.
or \( x' = \mathbf{H}x \), where \( \mathbf{H} \) is a \( 3 \times 3 \) non-singular homogeneous matrix.

- This is the most general transformation between the world and image plane under imaging by a perspective camera.
- It is often only the \( 3 \times 3 \) form of the matrix that is important in establishing properties of this transformation.
- A projective transformation is also called a “homography” and a “collineation”.
- \( \mathbf{H} \) has 8 degrees of freedom.
Four points define a projective transformation

**Given** $n$ point correspondences $(x, y) \leftrightarrow (x', y')$

**Compute** $H$ such that $x'_i = Hx_i$

- Each point correspondence gives two constraints
  
  \[
  x' = \frac{x'_1}{x'_3} = \frac{h_{11}x + h_{12}y + h_{13}}{h_{31}x + h_{32}y + h_{33}}, \quad y' = \frac{x'_2}{x'_3} = \frac{h_{21}x + h_{22}y + h_{23}}{h_{31}x + h_{32}y + h_{33}}
  \]

  and multiplying out generates two linear equations for the elements of $H$

  \[
  x' (h_{31}x + h_{32}y + h_{33}) = h_{11}x + h_{12}y + h_{13} \\
  y' (h_{31}x + h_{32}y + h_{33}) = h_{21}x + h_{22}y + h_{23}
  \]

- If $n \geq 4$ (no three points collinear), then $H$ is determined uniquely.

- The converse of this is that it is possible to transform any four points in general position to any other four points in general position by a projectivity.
Example 1: Removing Perspective Distortion

**Given:** the coordinates of four points on the scene plane

**Find:** a projective rectification of the plane

- This *rectification* does not require knowledge of *any* of the camera’s parameters or the pose of the plane.
- It is not always necessary to know coordinates for four points.
The Cone of Rays

An image is the intersection of a plane with the cone of rays between points in 3-space and the optical centre. Any two such “images” (with the same camera centre) are related by a planar projective transformation.

$$x' = Hx$$

e.g. rotation about the camera centre
Example 2: Synthetic Rotations

The synthetic images are produced by projectively warping the original image so that four corners of an imaged rectangle map to the corners of a rectangle. Both warpings correspond to a synthetic rotation of the camera about the (fixed) camera centre.
Two View Geometry

- Cameras \(P\) and \(P'\) such that
  \[ x = PX \quad x' = P'X \]

- Baseline between the cameras is non-zero.

Given an image point in the first view, where is the corresponding point in the second view?

What is the relative position of the cameras?

What is the 3D geometry of the scene?
Projective transformation between images induced by a plane

\[ x = H_{1\pi}x_\pi \quad x' = H_{2\pi}x_\pi \]

\[ x' = H_{2\pi}x_\pi \]

\[ = H_{2\pi}H_{1\pi}^{-1}x = Hx \]

- \( H \) can be computed from the correspondence of four points on the plane.
Given the image of a point in one view, what can we say about its position in another?

- A point in one image “generates” a line in the other image.
- This line is known as an epipolar line, and the geometry which gives rise to it is known as epipolar geometry.
The epipolar line $l'$ is the image of the ray through $x$.

The epipole $e'$ is the point of intersection of the line joining the camera centres—the baseline—with the image plane.

The epipole is also the image in one camera of the centre of the other camera.

All epipolar lines intersect in the epipole.
As the position of the 3D point $X$ varies, the epipolar planes “rotate” about the baseline. This family of planes is known as an epipolar pencil. All epipolar lines intersect at the epipole.
Epipolar geometry depends only on the relative pose (position and orientation) and internal parameters of the two cameras, i.e. the position of the camera centres and image planes. It does not depend on structure (3D points external to the camera).
Homogeneous Notation Interlude

- A line $l$ is represented by the homogeneous 3-vector

\[
\mathbf{l} = \begin{pmatrix} l_1 \\ l_2 \\ l_3 \end{pmatrix}
\]

for the line $l_1x + l_2y + l_3 = 0$. Only the ratio of the homogeneous line coordinates is significant.

- point on line: $\mathbf{l}^\top \mathbf{x} = 0$ or $\mathbf{l}^\top \mathbf{x} = 0$ or $\mathbf{x}^\top \mathbf{l} = 0$

- two points define a line: $l = p \times q$

- two lines define a point: $\mathbf{x} = \mathbf{l} \times \mathbf{m}$
Matrix notation for vector product

The vector product $\mathbf{v} \times \mathbf{x}$ can be represented as a matrix multiplication

$$\mathbf{v} \times \mathbf{x} = [\mathbf{v}] \times \mathbf{x}$$

where

$$[\mathbf{v}] \times = \begin{bmatrix}
0 & -v_z & v_y \\
v_z & 0 & -v_x \\
-v_y & v_x & 0
\end{bmatrix}$$

- $[\mathbf{v}] \times$ is a $3 \times 3$ skew-symmetric matrix of rank 2.
- $\mathbf{v}$ is the null-vector of $[\mathbf{v}] \times$, since $\mathbf{v} \times \mathbf{v} = [\mathbf{v}] \times \mathbf{v} = 0$. 
Algebraic representation - the **Fundamental Matrix**

\[ x'^\top F x = 0 \quad l' = F x \]

- \( F \) is a \( 3 \times 3 \) rank 2 homogeneous matrix
- \( F^\top e' = 0 \)
- It has 7 degrees of freedom
- Counting: \( 2 \times 11 - 15 = 7 \).
- Compute from 7 image point correspondences
Step 1: Point transfer via a plane \( x' = H_{\pi} x \)

Step 2 : Construct the epipolar line \( l' = e' \times x' = [e']_{\times} x' \)

\[
l' = [e']_{\times} H_{\pi} x = F x
\]

\[
F = [e']_{\times} H_{\pi}
\]

This shows that \( F \) is a \( 3 \times 3 \) rank 2 matrix.
Properties of $F$

- $F$ is a rank 2 homogeneous matrix with 7 degrees of freedom.

- **Point correspondence**: If $x$ and $x'$ are corresponding image points, then $x'^\top F x = 0$.

- **Epipolar lines**: 
  - $l' = Fx$ is the epipolar line corresponding to $x$.
  - $l = F^\top x'$ is the epipolar line corresponding to $x'$.

- **Epipoles**: 
  - $F e = 0$ and $F^\top e' = 0$

- **Computation from camera matrices $P, P'$**: 
  - $F = [P' c] \times P' P^+$, where $P^+$ is the pseudo-inverse of $P$, and $c$ is the centre of the first camera. Note, $e' = P' c$.
  - Canonical cameras, $P = [I \mid 0], P' = [M \mid m]$, 
    $F = [e'] \times M = M^{-\top} [e] \times$, where $e' = m$ and $e = M^{-1} m$. 
Given the fundamental matrix $F$ between two views, the homography induced by a world plane is

$$H = [e']_\times F + e'v^\top$$

where $v$ is the inhomogeneous 3-vector which parametrizes the 3-parameter family of planes.

e.g. compute plane from 3 point correspondences.

Given a homography $\hat{H}$ induced by a particular world plane, then a homography induced by any plane may be computed as

$$H = \hat{H} + e'v^*\top$$
Projective Reconstruction from 2 views
Statement of the problem

Given

Corresponding points $x_i \leftrightarrow x'_i$ in two images.

Find

Cameras $P$ and $P'$ and 3D points $x_i$ such that

$$x_i = Px_i \ ; \ x'_i = P'x_i$$
Projective ambiguity of reconstruction

- Solution is not unique without camera calibration
- Solution is unique up to a projective mapping:

\[
P \mapsto PH^{-1}
\]

\[
P' \mapsto P'H^{-1}
\]

\[
x_i \mapsto Hx_i
\]

Then verify

\[
x_i = (PH^{-1})(Hx_i) = Px_i
\]

\[
x'_i = (P'H^{-1})(Hx_i) = P'x_i
\]

- Same problem holds however many views we have
Projective Distortion demo

< Projective distortion demo >
Basic Theorem

Given sufficiently many points to compute unique fundamental matrix:

- 8 points in general position
- 7 points not on a ruled quadric with camera centres

Then 3D points may be constructed from two views Up to a 3D projective transformation

- Except for points on the line between the camera centres.
Steps of projective reconstruction

Reconstruction takes place in the following steps:

- Compute the fundamental matrix $F$ from point correspondences.
- Factor the fundamental matrix as $F = [t] \times M$.
- The two camera matrices are $P = [I \mid 0]$ and $P' = [M \mid t]$.
- Compute the points $x_i$ by triangulation.
Details of Projective Reconstruction - Computation of $F$.

Methods of computation of $F$ left until later.

Several methods are available:

(i) Normalized 8-point algorithm
(ii) Algebraic minimization
(iii) Minimization of epipolar distance
(iv) Minimization of symmetric epipolar distance
(v) Maximum Likelihood (Gold-standard) method.
(vi) Others, . . .
Factorization of the fundamental matrix

SVD method

(i) Define

\[ Z = \begin{bmatrix} 0 & 1 & 0 \\ -1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \]

(ii) Compute the SVD

\[ F = UDV^\top \text{ where } D = \text{diag}(r, s, 0) \]

(iii) Factorization is

\[ F = (UZU^\top)(UZDV^\top) \]

• Simultaneously corrects \( F \) to a singular matrix.
Factorization of the fundamental matrix

**Direct formula**

Let $e'$ be the epipole.

Solve $e'^\top F = 0$

**Specific formula**

$$P = [I \mid 0] ; \quad P' = [e' \times F \mid e'] = [M \mid e']$$

This solution is identical to the SVD solution.
Non-uniqueness of factorization

- Factorization of the fundamental matrix is not unique.
- General formula: for varying $\nu$ and $\lambda$
  \[ P = [I \mid 0] \; ; \; P' = [M + e'\nu^\top \mid \lambda e'] \]
- Difference factorizations give configurations varying by a projective transformation.
- 4-parameter family of solutions with $P = [I \mid 0]$.  

Triangulation

- Knowing $P$ and $P'$
- Knowing $x$ and $x'$
- Compute $x'$ such that

$$x = Px ; \quad x' = P'x$$
Triangulation in presence of noise

- In the presence of noise, back-projected lines do not intersect.

Rays do not intersect in space

Measured points do not lie on corresponding epipolar lines
Which 3D point to select?

- Mid-point of common perpendicular to the rays?  
  - **Not** a good choice in projective environment.  
  - Concepts of mid-point and perpendicular are meaningless under projective distortion.

- Weighted point on common perpendicular, weighted by distance from camera centres?  
  - Distance is also undefined concept.

- Some algebraic distance?  
  - Write down projection equations and solve?  
  - Linear least squares solution.  
  - Minimizes nothing meaningful.
Problem statement

- Assume camera matrices are given without error, up to projective distortion.
- Hence $F$ is known.
- A pair of matched points in an image are given.
- Possible errors in the position of matched points.
- Find 3D point that minimizes suitable error metric.
- Method must be invariant under 3D projective transformation.
Linear triangulation methods

- Direct analogue of the linear method of camera resectioning.
- Given equations

\[
\begin{align*}
  x &= P x \\
  x' &= P' x
\end{align*}
\]

- \( p_i^T \) are the rows of \( P \).
- Write as linear equations in \( x \)

\[
\begin{bmatrix}
  xp^3T - p^1T \\
  yp^3T - p^2T \\
  x'p'^3T - p'^1T \\
  yp'^3T - p'^2T
\end{bmatrix} \quad x = 0
\]

- Solve for \( x \).
- Generalizes to point match in several images.
- Minimizes no meaningful quantity – not optimal.
Minimizing geometric error

- Point $x$ in space maps to projected points $\hat{x}$ and $\hat{x}'$ in the two images.
- Measured points are $x$ and $x'$.
- Find $x$ that minimizes difference between projected and measured points.
Cost function

\[ C(x) = d(x, \hat{x})^2 + d(x', \hat{x}')^2 \]
Different formulation of the problem

Minimization problem may be formulated differently:

- Minimize
  \[ d(x, l)^2 + d(x', l')^2 \]
- \( l \) and \( l' \) range over all choices of corresponding epipolar lines.
- \( \hat{x} \) is the closest point on the line \( l \) to \( x \).
- Same for \( \hat{x}' \).
Minimization method

Our strategy for minimizing cost function is as follows

(i) Parametrize the pencil of epipolar lines in the first image by a parameter $t$. Epipolar line is $l(t)$.

(ii) Using the fundamental matrix $F$, compute the corresponding epipolar line $l'(t)$ in the second image.

(iii) Express the distance function $d(x, l(t))^2 + d(x', l'(t))^2$ explicitly as a function of $t$.

(iv) Find the value of $t$ that minimizes this function.
Minimization method ...

- Find the minimum of a function of a single variable, $t$.
- Problem in elementary calculus.
- Derivative of cost reduces to a $6$-th degree polynomial in $t$.
- Find roots of derivative explicitly and compute cost function.
- Provides global minimum cost (guaranteed best solution).
- Details: See Hartley-Sturm “Triangulation”.
Multiple local minima

- Cost function may have local minima.
- Shows that gradient-descent minimization may fail.

Left: Example of a cost function with three minima.

Right: Cost function for a perfect point match with two minima.
Uncertainty of reconstruction. The shape of the uncertainty region depends on the angle between the rays.

Computation of the Fundamental Matrix
Basic equations

Given a correspondence

\[ x \leftrightarrow x' \]

The basic incidence relation is

\[ x'^TFx = 0 \]

May be written

\[ x'xf_{11} + x'yf_{12} + x'f_{13} + y'x f_{21} + y'yf_{22} + y'f_{23} + xf_{31} + yf_{32} + f_{33} = 0 \].
Single point equation - Fundamental matrix

Gives an equation:

\[
\begin{pmatrix}
  f_{11} \\
  f_{12} \\
  f_{13} \\
  f_{21} \\
  f_{22} \\
  f_{23} \\
  f_{31} \\
  f_{32} \\
  f_{33}
\end{pmatrix} \cdot (x'x, x'y, x', y'x, y'y, y', x, y, 1) = 0
\]

where

\[
f = (f_{11}, f_{12}, f_{13}, f_{21}, f_{22}, f_{23}, f_{31}, f_{32}, f_{33})^T
\]

holds the entries of the Fundamental matrix
Total set of equations

\[ A \mathbf{f} = \begin{pmatrix} x_1' x_1 & x_1' y_1 & x_1' y_1' & x_1 & y_1 & y_1' & 1 \\ x_n' x_n & x_n' y_n & x_n' y_n' & x_n & y_n & y_n' & 1 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ x_1' x_1 & x_1' y_1 & x_1' y_1' & x_1 & y_1 & y_1' & 1 \\ y_1' y_1 & y_1' y_1' & y_1' y_1' & y_1 & y_1' & y_1' & 1 \\ \end{pmatrix} \begin{pmatrix} f_{11} \\ f_{12} \\ f_{13} \\ f_{21} \\ f_{22} \\ f_{23} \\ f_{31} \\ f_{32} \\ f_{33} \end{pmatrix} = 0 \]
Solving the Equations

- Solution is determined up to scale only.
- Need 8 equations $\Rightarrow$ 8 points
- 8 points $\Rightarrow$ unique solution
- $>8$ points $\Rightarrow$ least-squares solution.

Least-squares solution

(i) Form equations $Af = 0$.
(ii) Take SVD: $A = UDV^\top$.
(iii) Solution is last column of $V$ (corresp: smallest singular value).
(iv) Minimizes $||Af||$ subject to $||f|| = 1$. 
The singularity constraint

Fundamental matrix has rank 2: \( \det(F) = 0 \).

Left: Uncorrected \( F \) – epipolar lines are not coincident.

Right: Epipolar lines from corrected \( F \).
Computing $F$ from 7 points

- $F$ has 9 entries but is defined only up to scale.
- Singularity condition $\det F = 0$ gives a further constraint.
- $F$ has 3 rows $\implies \det F = 0$ is a cubic constraint.
- $F$ has only 7 degrees of freedom.
- It is possible to solve for $F$ from just 7 point correspondences.
7-point algorithm

Computation of $F$ from 7 point correspondences

(i) Form the $7 \times 9$ set of equations $A f = 0$.
(ii) System has a 2-dimensional solution set.
(iii) General solution (use SVD) has form

$$ f = \lambda f_0 + \mu f_1 $$

(iv) In matrix terms

$$ F = \lambda F_0 + \mu F_1 $$

(v) Condition $\det F = 0$ gives cubic equation in $\lambda$ and $\mu$.
(vi) Either one or three real solutions for ratio $\lambda : \mu$. 
Correcting $F$ using the Singular Value Decomposition

If $F$ is computed linearly from 8 or more correspondences, singularity condition does not hold.

**SVD Method**

(i) SVD: $F = UDV^\top$
(ii) $U$ and $V$ are orthogonal, $D = \text{diag}(r, s, t)$.
(iii) $r \geq s \geq t$.
(iv) Set $F' = U \text{diag}(r, s, 0) V^\top$.
(v) Resulting $F'$ is singular.
(vi) Minimizes the Frobenius norm of $F - F'$
(vii) $F'$ is the "closest" singular matrix to $F$. 
Complete 8-point algorithm

8 point algorithm has two steps:

(i) **Linear solution.** Solve \( Af = 0 \) to find \( F \).
(ii) **Constraint enforcement.** Replace \( F \) by \( F' \).

**Warning** This algorithm is unstable and should never be used with unnormalized data (see next slide).
The normalized 8-point algorithm

Raw 8-point algorithm performs badly in presence of noise.

Normalization of data

- 8-point algorithm is sensitive to origin of coordinates and scale.
- Data must be translated and scaled to “canonical” coordinate frame.
- Normalizing transformation is applied to both images.
- Translate so centroid is at origin
- Scale so that RMS distance of points from origin is \( \sqrt{2} \).
- “Average point” is \((1, 1, 1)^\top\).
Normalized 8-point algorithm

(i) Normalization: Transform the image coordinates:

\[
\hat{x}_i = Tx_i \\
\hat{x}_i' = T'x_i'
\]

(ii) Solution: Compute \( F \) from the matches \( \hat{x}_i \leftrightarrow \hat{x}_i' \)

\[
\hat{x}_i'^\top \hat{F} \hat{x}_i = 0
\]

(iii) Singularity constraint: Find closest singular \( \hat{F}' \) to \( \hat{F} \).

(iv) Denormalization: \( F = T'^\top \hat{F}' T \).
Comparison of Normalized and Unnormalized Algorithms
Litia House images
Statue images
Oxford Basement
Calibration object
Testing methodology

(i) Point matches found in image pairs and outliers discarded.
(ii) Fundamental matrix was found from varying number \((n)\) of points.
(iii) \(F\) was tested against other matched points not used to compute it.
(iv) Distance of a point from predicted epipolar line was the metric.
(v) 100 trials for each value of \(n\).
(vi) Average error is plotted against \(n\).
Comparison of normalized and unnormalized 8-point algorithms.

Distance of points from epipolar lines:

**Top**: Unnormalized 8-point algorithm.

**Bottom**: Normalized 8-point algorithm.
Comparison of normalized and unnormalized 8-point algorithms.

Distance of points from epipolar lines:

**Top**: Unnormalized 8-point algorithm.

**Bottom**: Normalized 8-point algorithm.
Comparison of normalized and unnormalized 8-point algorithms.

Distance of points from epipolar lines:

**Top**: Unnormalized 8-point algorithm.

**Bottom**: Normalized 8-point algorithm.
Illustration of Effect of Normalization

Similar problem: Computation of a 2D projective transformation given point matches in two images.

(i) Homography is computed from 5 noisy point matches.
(ii) Homography is applied to a further (6th) point
(iii) Noise level approximately equal to with of lines in the crosses (next page)
(iv) Repeated 100 times.
(v) Spread of the transformed 6th point is shown in relation to the 5 data points.
(vi) 95% ellipses are plotted.
Normalization and 2D homography computation

Unnormalized data

Normalized data
Normalization and 2D homography computation

Unnormalized data

Normalized data
Condition number

- Bad condition number the reason for poor performance.
- Condition number $= \kappa_1/\kappa_8$, ratio of singular values of $A$.

- Bad conditioning acts as a noise amplifier.
- Normalization improves the condition number by a factor of $10^8$.
- Reference: Hartley "In defence of the 8-point algorithm".
Algebraic Minimization Algorithm
Enforcing the singularity constraint

- SVD method minimizes $|F' - F|$.  
- Simple and rapid. 
- Not optimal 
- Treats all entries of $F$ equally.  
- However, some entries of $F$ are more tightly constrained by the data.
The Algebraic Method

- Minimize $\|Af'\|$ subject to $\|f'\| = 1$ AND $\det F' = 0$.
- $\det F' = 0$ is a cubic constraint.
- Requires an iterative solution.
- However, simple iterative method works.
Solution assuming known epipole

- We may write $F = M[e] \times$, where $e$ is epipole.
- $F$ of this form is singular.
- Assume $e$ is known, find $M$.
- Write $F = M[e] \times$ as $f = Em$

\[
\begin{pmatrix}
  f_{11} \\
  f_{12} \\
  f_{13} \\
  f_{21} \\
  f_{22} \\
  f_{23} \\
  f_{31} \\
  f_{32} \\
  f_{33}
\end{pmatrix} =
\begin{bmatrix}
  0 & -e_3 & e_2 \\
  e_3 & 0 & -e_1 \\
  -e_2 & e_1 & 0 \\
  0 & -e_3 & e_2 \\
  e_3 & 0 & -e_1 \\
  -e_2 & e_1 & 0 \\
  0 & -e_3 & e_2 \\
  e_3 & 0 & -e_1 \\
  -e_2 & e_1 & 0
\end{bmatrix}
\begin{pmatrix}
  m_{11} \\
  m_{12} \\
  m_{13} \\
  m_{21} \\
  m_{22} \\
  m_{23} \\
  m_{31} \\
  m_{32} \\
  m_{33}
\end{pmatrix}
\]
Solution assuming known epipole - continued

- Write $Af = AE\text{m}$.
- Minimize $||AE\text{m}||$ subject to $||\text{Em}|| = 1$.
- This is a linear least-squares estimation problem.
- Non-iterative algorithm involving SVD is possible.
Iterative Algebraic Estimation

Find the fundamental matrix $F$ that minimizes the algebraic error $||Af||$ subject to $||f|| = 1$ and $\det F = 0$.

- **Concept:** Vary epipole $e$ to minimize the algebraic error $||Af'|| = ||AEm||$.
- **Remark:** Each choice of epipole $e$ defines a minimum error vector $AEm$ as above.
- Use Levenberg-Marquardt method to minimize this error.
- Simple $3 \times 9$ minimization problem.
  - 3 inputs – the coordinates of the epipole
  - 9 outputs – the algebraic error vector $Af' = AEm$.
- Each step requires estimation of $m$ using SVD method.
- Tricks can be used to avoid SVD (see Hartley-Royal-Society).
Minimization of Geometric Error
Minimization of Geometric Error

- Algebraic error vector $\Delta f$ has no clear geometric meaning.
- Should be minimizing geometric quantities.
- Errors derive from incorrect measurements of match points.

- We should be measuring distances from epipolar lines.
The Gold Standard (ML) Method

- Assumes a Gaussian distributed noise.
- Measured correspondences \( x_i \leftrightarrow x'_i \).
- Estimated correspondences \( \hat{x}_i \) and \( \hat{x}'_i \)

\[
\sum_i d(x_i, \hat{x}_i)^2 + d(x'_i, \hat{x}'_i)^2
\]

subject to \( \hat{x}'_i \top F \hat{x}_i = 0 \) exactly for some \( F \).
- Simultaneous estimation of \( F \) and \( \hat{x}_i \) and \( \hat{x}'_i \).
The Gold Standard (ML) Method

Minimizing the Gold-Standard error function.

- Initial 3D reconstruction:
  \[ P = \begin{bmatrix} I & 0 \end{bmatrix} \]
  \[ P' = \begin{bmatrix} M & t \end{bmatrix} \]
  \[ x_i = (X_i, Y_i, 1, T_i)^\top \]

- Compute \( \hat{x}_i = Px_i = (X_i, Y_i, 1)^\top \) and \( \hat{x}'_i = P'x_i \).
- Iterate over \( P' \) and \( x_i = (X_i, Y_i, 1, T_i)^\top \) to minimize cost function:
  \[ \sum_i d(x_i, \hat{x}_i)^2 + d(x'_i, \hat{x}'_i)^2 \]

- Total of \( 3n + 12 \) parameters.
  - 12 parameters for the camera matrix \( P' \)
  - 3 parameters for each point \( x_i \).
  - Once \( P' = [M | t] \) is found, compute \( F = [t] \times M \).
Sparse Levenberg-Marquardt

Reference: Hartley-Azores

(i) Coordinates of \( x_i \) do not affect \( \hat{x}_j \) or \( \hat{x}'_j \) (for \( i \neq j \)).
(ii) Sparse LM takes advantage of sparseness
(iii) Linear time in \( n \) (number of points).
(iv) Reference: Hartley-Azores
Parametrization of rank-2 matrices

- Estimation of $F$ may be done by parameter minimization.
- Parametrize $F$ such that $\det F = 0$.
- Various parametrizations have been used.

**Overparametrization.**

- Write $F = [t] \times M$.
- 3 parameters for $t$ and 9 for $M$.

**Epipolar parametrization.**

$$F = \begin{bmatrix} a & b & \alpha a + \beta b \\ c & d & \alpha c + \beta d \\ e & f & \alpha e + \beta f \end{bmatrix}$$

To achieve a minimum set of parameters, set one of the elements, for instance $f$ to 1.
Both epipoles as parameters. The resulting form of $F$ is

$$F = \begin{bmatrix} a & b & \alpha a + \beta b \\ c & d & \alpha c + \beta d \\ \alpha' a + \beta' c & \alpha' b + \beta' d & \alpha' \alpha a + \alpha' \beta b + \beta' \alpha c + \beta' \beta d \end{bmatrix}$$
Epipolar distance

- Point correspondence \( x' \leftrightarrow x \) :
- Point \( x \) \( \mapsto \) epipolar line \( Fx \).
- Epipolar distance is distance of point \( x' \) to epipolar line \( Fx \).
- Write \( Fx = (\lambda, \mu, \nu)\top \) and \( x' = (x', y', 1)\top \).
- Distance is

\[
d(x', Fx) = x'\top Fx(\lambda^2 + \mu^2)^{-1/2}
\]
Epipolar distance - continued

• Epipolar distance may be written as

\[ d(x', Fx) = \frac{x'^\top Fx}{((Fx)^2_1 + (Fx)^2_2)^{1/2}} \]

• Total cost function:

\[ \sum_i d(x'_i, Fx_i)^2 = \sum_i \frac{(x'_i\top Fx_i)^2}{(Fx_i)^2_1 + (Fx_i)^2_2} \]

• Total cost: sum over all \( x'_i \leftrightarrow x_i \).

• Minimize this cost function over parametrization of \( F \).
Symmetric epipolar distance

- Epipolar distance function is not symmetric.
- Prefer sum of distances in both images.
- Symmetric cost function is
  \[ d(x', Fx)^2 + d(x, F^\top x')^2 \]
- Sum over all points :
  \[ \text{Cost} = \sum_i (x'_i F x_i)^2 \left( \frac{1}{(Fx_i)_1^2 + (Fx_i)_2^2} + \frac{1}{(F^\top x'_i)_1^2 + (F^\top x'_i)_2^2} \right) \]

Problem

- Points near the epipole have a disproportionate influence.
- Small deviation in point makes big difference to epipolar line.
Luong / Zhang’s other error function

\[ \sum_i \frac{(x'_i^\top F x_i)^2}{(F x_i)_1^2 + (F x_i)_2^2 + (F^\top x'_i)_1^2 + (F^\top F x'_i)_2^2} \]

Represents a first-order approximation to geometric error.

More Algorithm Comparison
Experimental Evaluation of the Algorithms

Three of the algorithms compared

(i) The normalized 8-point algorithm
(ii) Minimization of algebraic error whilst imposing the singularity constraint
(iii) The Gold Standard geometric algorithm
Experimental procedure

(i) Find matched points in image pair.
(ii) Select $n$ matched points at random
(iii) Compute the fundamental matrix
(iv) Compute epipolar distance for all other points.
(v) Repeat 100 times for each $n$ and collect statistics.

The error is defined as

$$\frac{1}{N} \sum_{i}^{N} (d(x'_i, Fx_i) + d(x_i, F^\top x'_i))$$

i.e Average symmetric epipolar distance.
Results

Normalized 8-point, geometric and algebraic error.
Normalized 8-point, geometric and algebraic error.
Results - continued

Normalized 8-point, geometric and algebraic error.
Covariance computation
To compute the covariance matrix of the entries of $P'$:

(i) Define $Q = (x_i, x'_i)^\top$ — vector of measurements in both images.

(ii) Compute the derivative matrices

$$A_i = \left[ \frac{\partial \hat{Q}_i}{\partial P'} \right] \quad \text{and} \quad B_i = \left[ \frac{\partial \hat{Q}_i}{\partial x_i} \right]$$

(iii) Compute in steps

$$U = \sum_i A_i^\top \Sigma_{Q_i}^{-1} A_i$$

$$V_i = B_i^\top \Sigma_{Q_i}^{-1} B_i$$

$$W_i = A_i^\top \Sigma_{Q_i}^{-1} B_i$$

$$\Sigma_{P'} = (U - \sum_i W_i V_i^{-1} W_i^\top)^+ \quad \text{(pseudo-inverse)}$$
Covariance of $F$

To compute the covariance of $F$:

(i) Given $P' = [M \mid m]$, then $F = [m]_xM$.

(ii) Compute $J = \partial F / \partial P'$.

(iii) $\Sigma_F = J\Sigma_{P'}J^\top$

Covariance of epipolar line corresponding to $x$

(i) Epipolar line is $l = Fx$.

(ii) Given $x$ and $\Sigma_F$ compute $J = \partial l / \partial F$

(iii) $\Sigma_l = J\Sigma_FJ^\top$
The envelope of epipolar lines

• May compute envelope of epipolar lines.

\[ C = \bar{I} \bar{I}^\top - k^2 \Sigma_1 \]

• \( C \) is a hyperbola that contains the epipolar line with a given probability \( \alpha \).

• \( k^2 \) chosen such that \( F^{-1}_2(k^2) = \alpha \),

• \( F_2(k^2) \) represents the cumulative \( \chi^2 \) distribution,

• with probability \( \alpha \) the lines lie within this region.

< epipolar line demonstration here >
Using special motions can simplify the computation of the fundamental matrix.
Pure translation

- Can assume $P = [I|0]$ and $P' = [I|t]$.
- $F = [t]_\times$.
- $F$ is skew-symmetric – has 2 dof.
- Being skew-symmetric, automatically has rank 2.

For a pure translation the epipole can be estimated from the image motion of two points.
Cameras with the same principal plane

- Principal plane of the camera is the third row of $P$.
- Cameras have the same third row.
- Affine cameras - last row is $(0, 0, 0, 1)^T$.

Simple correspondences exist:

$$(x', y', 0)F(x, y, 0)^\top = 0$$

for any $(x', y', 0)^\top$ and $(x, y, 0)^\top$.

$F$ has the following form:

$$F = \begin{bmatrix} a \\ b \\ c & d & e \end{bmatrix}$$
Degeneracies

Correspondences are degenerate if they satisfy more than one $F$.

\[ x_i^\top F_1 x_i^\top = 0 \quad \text{and} \quad x'_i F_2 x_i = 0 \quad (1 \leq i \leq n) \]
(i) If all the points and the two camera centres lie on a ruled quadric, then there are three possible fundamental matrices.

(ii) points lie in a plane. The correspondences \( x_i \leftrightarrow x'_i \) lead to a 3-parameter family of possible fundamental matrices \( F \) (note, one of the parameters accounts for scaling the matrix so there is only a two-parameter family of homogeneous matrices).

(iii) Two cameras at the same point :
- The fundamental matrix does not exist.
- There is no such thing as an epipolar plane, and epipolar lines are not defined.
- Correspondences \( x'_i \leftrightarrow x_i \) give at least a 2-parameter family of \( F \).
This page left empty
Automatic Estimation of Epipolar Geometry
Problem Statement

**Given** Image pair

![Image pair](image1.jpg) ![Image pair](image2.jpg)

**Find** The fundamental matrix $F$ and correspondences $x_i \leftrightarrow x'_i$.

- Compute image points
- Compute correspondences
- Compute epipolar geometry
Robust line estimation

Fit a line to 2D data containing outliers

There are two problems:

(i) a line fit to the data \( \min_1 \sum_i d_{\perp i}^2 \); and,

(ii) a classification of the data into inliers (valid points) and outliers.
RANdom SAmple Consensus (RANSAC)

[Fischler and Bolles, 1981]

Objective  Robust fit of a model to a data set $S$ which contains outliers.

Algorithm

(i) Randomly select a sample of $s$ data points from $S$ and instantiate the model from this subset.

(ii) Determine the set of data points $S_i$ which are within a distance threshold $t$ of the model. The set $S_i$ is the consensus set of the sample and defines the inliers of $S$.

(iii) If the size of $S_i$ (the number of inliers) is greater than some threshold $T$, re-estimate the model using all the points in $S_i$ and terminate.

(iv) If the size of $S_i$ is less than $T$, select a new subset and repeat the above.

(v) After $N$ trials the largest consensus set $S_i$ is selected, and the model is re-estimated using all the points in the subset $S_i$. 
Robust ML estimation

An improved fit by

• A better minimal set
• Robust MLE: instead of $\min_1 \sum_i d_{\perp i}^2$

$$\min_1 \sum_i \gamma(d_{\perp i}) \quad \text{with} \quad \gamma(e) = \begin{cases} e^2 & e^2 < t^2 \text{ inlier} \\ t^2 & e^2 \geq t^2 \text{ outlier} \end{cases}$$
Feature extraction: “Corner detection”

Interest points [Harris]

- 100s of points per image
Correlation matching

- Match each corner to most similar looking corner in the other image
- Many wrong matches (10-50%), but enough to compute the fundamental matrix.
Correspondences consistent with epipolar geometry

- Use **RANSAC** robust estimation algorithm
- Obtain correspondences $x_i \leftrightarrow x_i'$ and $F$
- Guided matching by epipolar line
- Typically: final number of matches is about 200-250, with distance error of $\sim 0.2$ pixels.
Automatic Estimation of $F$ and correspondences

Algorithm based on RANSAC [Torr]

(i) Interest points: Compute interest points in each image.

(ii) Putative correspondences: use cross-correlation and proximity.

(iii) RANSAC robust estimation:
Repeat
  (a) Select random sample of 7 correspondences
  (b) Compute $F$
  (c) Measure support (number of inliers)
Choose the $F$ with the largest number of inliers.

(iv) MLE: re-estimate $F$ from inlier correspondences.

(v) Guided matching: generate additional matches.
How many samples?

For probability $p$ of no outliers:

$$N = \log(1 - p) / \log(1 - (1 - \epsilon)^s)$$

- $N$, number of samples
- $s$, size of sample set
- $\epsilon$, proportion of outliers

### Sample size vs. Proportion of outliers $\epsilon$

Part 2: Three-view and Multiple-view Geometry

Computing a Metric Reconstruction
Reconstruction from two views

Given only image points and their correspondence, what can be determined?
Two View Reconstruction Ambiguity

Given: image point correspondences $x_i \leftrightarrow x'_i$,
compute a reconstruction:

$$\{P, P', X_i\} \quad \text{with} \quad x_i = PX_i \quad x'_i = P'X_i$$

Ambiguity

$$x_i = PX_i = P H(H)^{-1} X_i = \tilde{P} \tilde{X}_i$$

$$x'_i = P'X_i = P' H(H)^{-1} X_i = \tilde{P}' \tilde{X}_i$$

$$\{\tilde{P}, \tilde{P}', \tilde{X}_i\}$$ is an equivalent Projective Reconstruction.
Metric Reconstruction

Correct: angles, length ratios.
Algebraic Representation of Metric Reconstruction

Compute $H$

$$\{P^1, P^2, ..., P^m, X_i\} \xrightarrow{H} \{P^1_M, P^2_M, ..., P^m_M, X^M_i\}$$

- Projective Reconstruction
- Metric Reconstruction

- Remaining ambiguity is rotation (3), translation (3) and scale (1).
- Only 8 parameters required to rectify entire sequence ($15 - 7 = 8$).

How?

- Calibration points: position of 5 scene points.
- Scene geometry: e.g. parallel lines/planes, orthogonal lines/planes, length ratios.
- Auto-calibration: e.g. camera aspect ratio constant for sequence.
Projective Reconstruction
Direct Metric Reconstruction

Use 5 or more 3D points with known Euclidean coordinates to determine $H$. 
Stratified Reconstruction

Given a projective reconstruction \( \{P_j, x_i\} \), compute a metric reconstruction via an intermediate affine reconstruction.

(i) affine reconstruction: Determine the vector \( p \) which defines \( \pi_\infty \). An affine reconstruction is obtained as \( \{P_jH_P, H_P^{-1}x_i\} \) with

\[
H_P = \begin{bmatrix}
I & 0 \\
-p^\top & 1
\end{bmatrix}
\]

(ii) Metric reconstruction: is obtained as \( \{P_j^AH_A, H_A^{-1}x_A\} \) with

\[
H_A = \begin{bmatrix}
K & 0 \\
0 & 1
\end{bmatrix}
\]
Stratified Reconstruction

- Start with a projective reconstruction.
- Find transformation to upgrade to affine reconstruction.
  - Equivalent to finding the plane at infinity.
- Find transformation to upgrade to metric (Euclidean) reconstruction.
  - Equivalent to finding the “absolute conic”
- Equivalent to camera calibration
  - If camera calibration is known then metric reconstruction is possible.
  - Metric reconstruction implies knowledge of angles – camera calibration.
Anatomy of a 3D projective transformation

- General 3D projective transformation represented by a $4 \times 4$ matrix.

$$H = \begin{bmatrix} sR K & t \\ v^\top & 1 \end{bmatrix} = \begin{bmatrix} sR & t \\ 1 \\ K \\ v^\top \end{bmatrix} \begin{bmatrix} I \\ v^\top & 1 \end{bmatrix} = \text{metric} \times \text{affine} \times \text{projective}$$
(i) Apply the transformations one after the other:

- Projective transformation – reduce to affine ambiguity
  \[
  \begin{bmatrix}
  I \\
  v^T \ 1
  \end{bmatrix}
  \]

- Affine transformation – reduce to metric ambiguity
  \[
  \begin{bmatrix}
  K \\
  1
  \end{bmatrix}
  \]

- Metric ambiguity of scene remains
Reduction to affine

Affine reduction using scene constraints - parallel lines
Reduction to affine

Other scene constraints are possible:

- Ratios of distances of points on line (e.g. equally spaced points).
- Ratios of distances on parallel lines.

Points lie in front of the viewing camera.

- Constrains the position of the plane at infinity.
- Linear-programming problem can be used to set bounds on the plane at infinity.
- Gives so-called “quasi-affine” reconstruction.
Common calibration of cameras.

- With 3 or more views, one can find (in principle) the position of the plane at infinity.
- Iteration over the entries of projective transform: \( \begin{bmatrix} I \\ v^\top \end{bmatrix} = \begin{bmatrix} 1 \\ v^\top \end{bmatrix} \).
- Not always reliable.
- Generally reduction to affine is difficult.
Metric Reconstruction
Assume plane at infinity is known.

- Wish to make the step to metric reconstruction.
- Apply a transformation of the form \[
\begin{bmatrix}
  K \\
  1
\end{bmatrix}
\]
- Linear solution exists in many cases.
The Absolute Conic

- Absolute conic is an imaginary conic lying on the plane at infinity.
- Defined by
  \[ \Omega : x^2 + y^2 + z^2 = 0 ; \ T = 0 \]
- Contains only imaginary points.
- Determines the Euclidean geometry of the space.
- Represented by matrix \( \Omega = \text{diag}(1, 1, 1, 0) \).
- Image of the absolute conic (IAC) under camera \( P = K[R \ | \ t] \) is given by \( \omega = (KK^\top)^{-1} \).
- Basic fact:
  \[
  \omega \text{ is unchanged under camera motion.}
  \]
Using the infinite homography

(i) When a camera moves, the image of a plane undergoes a projective transformation.

(ii) If we have affine reconstruction, we can compute the transformation $H$ of the plane at infinity between two images.

(iii) Absolute conic lies on the plane at infinity, but is unchanged by this image transformation:

(iv) Transformation rule for dual conic $\omega^* = \omega^{-1}$.

$$\omega^* = H_j \omega^* H_j^\top$$

(v) Linear equations on the entries of $\omega^*$.

(vi) Given three images, solve for the entries of $\omega^*$.

(vii) Compute $K$ by Choleski factorization of $\omega^* = KK^\top$. 
Example of calibration

Images taken with a non-translating camera:
Mosaiced image showing projective transformations
Computation of $K$

Calibration matrix of camera is found as follows:

- Compute the homographies (2D projective transformations) between images.
- Form equations
  \[ \omega^* = H_{ij} \omega^* H_{ij}^\top \]
- Solve for the entries of $\omega^*$
- Choleski factorization of $\omega^* = KK^\top$ gives $K$. 

Principal is the same for non-stationary cameras once principal plane is known.

- $H_{ij}$ is the “infinite homography” (i.e. via the plane at infinity) between images $i$ and $j$.
- May be computed directly from affinely-correct camera matrices.
- Given camera matrices

$$P_i = [M_i | t_i] ; \quad P_i = [M_i' | t_i]$$

- Infinite homography is given by

$$H = M_i'M^{-1}$$

- Algorithm proceeds as for fixed cameras.
The previous calibration procedure (affine-to-metric) may be generalized to case of changing internal parameters.

See paper tomorrow given by Agapito.

The Trifocal Tensor
The Trifocal Tensor

(i) Defined for three views.
(ii) Plays a similar rôle to Fundamental matrix for two views.
(iii) Unlike fundamental matrix, trifocal tensor also relates lines in three views.
(iv) Mixed combinations of lines and points are also related.
Geometry of three views

Point-line-line incidence.

- Correspondence $x \leftrightarrow l' \leftrightarrow l''$
- Let $l^{(1)}$ and $l^{(2)}$ be two lines that meet in $x$.
- General line $l$ back-projects to a plane $l^T P$.
- Four plane are $l^{(1)^T} P$, $l^{(2)^T} P'$, $l'^T P'$ and $l''^T P''$
- The four planes meet in a point.
The trifocal relationship

Four planes meet in a point means determinant is zero.

\[
\begin{bmatrix}
    l^{(1)^\top} P \\
    l^{(2)^\top} P \\
    l' P' \\
    l'' P''
\end{bmatrix}
\]

- This is a linear relationship in the line coordinates.
- Also (less obviously) linear in the entries of the point \( x = l^{(1)} \times l^{(2)} \).

This is the trifocal tensor relationship.
Tensor Notation

Point coordinates.

- Consider basis set \((e_1, e_2, e_3)\).
- Point is represented by a vector \(x = (x^1, x^2, x^3)^\top\).
- New basis : \(\hat{e}_j = \sum_i H_{ij} e_i\).
- With respect to new basis \(x\) represented by
  \[
  \hat{x} = (\hat{x}^1, \hat{x}^2, \hat{x}^3) \text{ where } \hat{x} = H^{-1}x
  \]
- If basis is transformed according to \(H\), then point coordinates transform according to \(H^{-1}\).
- Terminology : \(x^i\) transforms contravariantly.
- Use upper indices for *contravariant* quantities.
Line coordinates

- Line is represented by a vector $\mathbf{l} = (l_1, l_2, l_3)$
- In new coordinate system $\hat{e}_j$, line has coordinate vector $\hat{\mathbf{l}}$, 
  $$\hat{\mathbf{l}}^\top = \mathbf{l}^\top H$$
- Line coordinates transform according to $H$.
- Preserves incidence relationship. Point lies on line if:
  $$\hat{\mathbf{l}}^\top \hat{x} = (\mathbf{l}^\top H)(H^{-1}x) = \mathbf{l}^\top x = 0$$
- Terminology: $l_j$ transforms covariantly.
- Use lower indices for covariant quantities.
Summation notation

- Repeated index in upper and lower positions implies summation.

Example

Incidence relation is written \( l_ix^i = 0 \).

Transformation of covariant and contravariant indices

Contravariant transformation

\[ \hat{x}^j = (H^{-1})^j_i x^i \]

Covariant transformation

\[ \hat{l}_j = H^i_j l_i \]
More transformation examples

Camera mapping has one covariant and one contravariant index: \( P_j^i \). Transformation rule \( \hat{P} = G^{-1}PF \) is

\[
\hat{P}_i^j = (G^{-1})^j_s P^s_r F^r_i
\]

Trifocal tensor \( T_{ij}^{jk} \) has one covariant and two contravariant indices. Transformation rule:

\[
\hat{T}_{ij}^{jk} = F_i^r (G^{-1})^j_s (H^{-1})^k_t T_{rt}^{st}
\]
The $\epsilon$ tensor

Tensor $\epsilon_{rst}$ :

- Defined for $r, s, t = 1, \ldots, 3$

  $$
  \epsilon_{rst} = \begin{cases} 
  0 & \text{unless } r, s \text{ and } t \text{ are distinct} \\
  +1 & \text{if } rst \text{ is an even permutation of } 123 \\
  -1 & \text{if } rst \text{ is an odd permutation of } 123
  \end{cases}
  $$

- Related to the cross-product :

  $$
  \mathbf{c} = \mathbf{a} \times \mathbf{b} \iff c_i = \epsilon_{ijk}a^jb^k.
  $$
Basic Trifocal constraint

Basic relation is a point-line-line incidence.

- Point $x^i$ in image 1
- lines $l'_j$ and $l''_k$ in images 2 and 3.
Basic Trifocal constraint . . .

• Let $l_r^{(1)}$ and $l_s^{(2)}$ be two lines that meet in point $x^i$.
• The four lines $l_r^{(1)}$, $l_s^{(2)}$, $l'_j$ and $l''_k$ back-project to planes in space.
• The four planes meet in a point.
Derivation of the basic three-view relationship

- Line $l_i$ back-projects to plane $l_i P^i$ where $P^i$ is $i$-th row.
- Four planes are coincident if
  $$(l^{(1)}_r P^r) \land (l^{(2)}_s P^s) \land (l^{(j)}_j P^j) \land (l^{(k)}_k P^k) = 0$$
  where 4-way wedge $\land$ means determinant.
- Thus
  $$l^{(1)}_r l^{(2)}_s l^{(j)}_j l^{(k)}_k P^r \land P^s \land P^j \land P^k = 0$$
- Multiply by constant $\epsilon^{rsi} \epsilon_{rsi}$ gives
  $$(\epsilon^{rsi} l^{(1)}_r l^{(2)}_s l^{(j)}_j l^{(k)}_k P^r \land P^s \land P^j \land P^k) = 0$$
- Intersection (cross-product) of $l^{(1)}_r$ and $l^{(2)}_s$ is the point $x^i :$
  $$l^{(1)}_r l^{(2)}_s \epsilon^{rsi} = x^i$$
Definition of the trifocal tensor

Basic relationship is

\[ x^i l'_j l''_k \epsilon_{rsi} P^r \wedge P^s \wedge P'^j \wedge P''^k = 0 \]

Define

\[ \epsilon_{rsi} P^r \wedge P^s \wedge P'^j \wedge P''^k = T^{jk}_i \]

Point-line-line relation is

\[ x^i l'_j l''_k T^{jk}_i = 0 \]

\( T^{jk}_i \) is covariant in one index \((i)\), contravariant in the other two.
Line Transfer

Basic relation is

\[ x^i l'_j l''_k T_{ij}^{j_k} = 0 \]

Interpretation:

- Back projected ray from \( x \) meets intersection of back-projected planes from \( l' \) and \( l'' \).
- Line in space projects to lines \( l' \) and \( l'' \) and to a line passing through \( x \).
Line transfer

- Denote $l_i = l'_j l''_k T^j_k i$
- See that $x^i l_i = 0$ when $x^i$ lies on the projection of the intersection of the planes.
- Thus $l_i$ represents the transferred line corresponding to $l'_j$ and $l''_k$.
- We write

$$l_i \approx l'_j l''_k T^j_k i$$

- Cross-product of the two sides are equal:

$$l_r \epsilon^{irs} l'_j l''_k T^j_k i = 0^s$$

- Derived from basic relation $x^i l'_j l''_k T^j_k i$ by replacing $x^i$ by $l_r \epsilon^{irs}$. 
- Line 1' back-projects to a plane $\pi'$.
- Ray from $x$ meets $\pi'$ in a point $x$.
- This point projects to point $x''$ in the third image.
- For fixed 1', mapping $x \mapsto x''$ is a homography.
Point-transfer and the trifocal tensor

- If \( l'' \) is any line through \( x'' \), then trifocal condition holds.
  \[ l''_k (x_i' l'_j T^{jk}_i) = 0 \]

- \( x^i l'_j T^{jk}_i \) must represent the point \( x'''_k \).
  \[ x'''_k \approx x^i l'_j T^{jk}_i \]

- Alternatively (cross-product of the two sides)
  \[ x^i l'_j \epsilon_{krs} x'''_r T^{jk}_i = 0_s \]

- Derived from basic relation \( x^i l'_j l''_k T^{jk}_i \) by replacing \( l''_k \) by \( x'''_r \epsilon_{krs} \).
Contraction of trifocal tensor with a line

- Write $H_i^k = l_j' T_i^{jk}$
- Then $x'^{ik} = H_i^k x^i$.
- $H_i^k$ represents the homography from image 1 to image 3 via the plane of the line $l_j'$.
Three-point correspondence

Given a triple correspondence $x \leftrightarrow x' \leftrightarrow x''$

- Choose any lines $l'$ and $l''$ passing through $x'$ and $x''$
- Trifocal condition holds

$$x^i l'_j l'_k T_{ij}^{jk} = 0$$
Geometry of the three-point correspondence

- 4 choices of lines $\Rightarrow$ 4 equations.
- May also be written as

$$x^i x'^r \epsilon_{r s i} x''^t \epsilon_{t u j} T_{i}^{j k} = 0$$

- Gives 9 equations, only 4 linearly independent.
Summary of transfer formulas

(i) Point transfer from first to third view via a plane in the second.

\[ x''^k = x'^i l'_j T^{jk}_i \]

(ii) Point transfer from first to second view via a plane in the third.

\[ x'^j = x^i l''^k T^{jk}_i \]

(iii) Line transfer from third to first view via a plane in the second; or, from second to first view via a plane in the third.

\[ l_i = l'_j l''^k T^{jk}_i \]
Summary of incidence relations

(i) Point in first view, lines in second and third

\[ l_j' l_k'' T_{i}^{jk} x^i = 0 \]

(ii) Point in first view, point in second and line in third

\[ x^i x^j' l_k'' \epsilon_{jpr} T_{i}^{pk} = 0_r \]

(iii) Point in first view, line in second and point in third

\[ x^i l_j' x^k'' \epsilon_{kqs} T_{i}^{jq} = 0_s \]

(iv) Point in three views

\[ x^i x^j' x^k'' \epsilon_{jpr} \epsilon_{kqs} T_{i}^{pq} = 0_{rs} \]
• Degeneracy of line transfer for corresponding epipolar lines.
• When the line lies in an epipolar plane, its position cannot be inferred from two views.
• Hence it cannot be transferred to a third view.
Degeneracy of point transfer

Transferring points from images 1 and 2 to image 3:

Only points that can not be transferred are those points on the baseline between centres of cameras 1 and 2.

For transfer with fundamental matrix, points in the trifocal plane cannot be transferred.
Contraction on a point

In $x''_k \approx x^i l'_j T^j_k$ write $x^i T^j_k = G^{jk}$

- Represents a mapping from line $l''_k$ to the point $x'_j$:

$$x''_k \approx G^{jk} l'_j = (x^i T^j_k) l'_j$$

- As $l'_j$ varies $x''_k$ traces out the projection of the ray through $x^i$.
- Epipolar line in third image.
- Epipole is the intersection of these lines for varying $x^i$. 
Finding epipolar lines

To find the epipolar line corresponding to a point $x^i$:

- Transfer to third image via plane back-projected from $l'_{j}$

$$x''_k = x^i T^j_{ik} l'_{j}$$

- Epipolar line satisfies $l''_k x'''^k = 0$ for each such $x''_k$.
- For all $l'_{j}$

$$x^i l'_{j} l''_k T^j_{ik} = 0$$

- Epipolar line corresponding to $x^i$ found by solving

$$l''_k (x^i T^j_{ik}) = 0^j$$

Result: Epipole is the common perpendicular to the null-space of all $x^i T^j_{ik}$.

Extraction of camera matrices from trifocal tensor
Formula for Trifocal tensor

- Trifocal tensor is independent of projective transformation.
- May assume that first camera is $[I \mid 0]$
- Other cameras are $[A \mid a_4]$ and $[B \mid b_4]$
- Formula

$$T_{ik}^j = a_i^j b_k^i - a_4^j b_i^k$$

- Note: $a_4$ and $b_4$ represent the epipoles:
  - Centre of the first camera is $(0, 0, 0, 1)$.
  - Epipole is image of camera centre.

$$a_4 = [A \mid a_4] \begin{pmatrix} 0 \\ 0 \\ 0 \\ 1 \end{pmatrix}$$
Where does this formula come from?

Formula for trifocal tensor

\[ T_{i}^{jk} = \epsilon_{rsi} P^r \wedge P^s \wedge P^{ij} \wedge P^{ik} \]

\[ = 2 \det \begin{bmatrix} \sim P_i \\ P^{ij} \\ P^{ik} \end{bmatrix} \]

Notation: \( \sim P^i \) means omit row \( i \).

Example, when \( i = 1 \)

\[ T_1^{jk} = \det \begin{bmatrix} 1 \\ a_j^1 a_j^2 a_j^3 a_j^4 \\ b_k^1 b_k^2 b_k^3 b_k^4 \end{bmatrix} \]

\[ = a_1^j b_4^k - a_4^j b_1^k \]
Extraction of the camera matrices.

Basic formula

\[ T_{ij}^{jk} = a^j_i b^k_4 - a^j_4 b^k_i \]

- Entries of \( T_{ij}^{jk} \) are quadratic in the entries of camera matrices.
- **But** if epipoles \( a^j_4 \) and \( b^k_4 \) are known, entries are linear.

Strategy :

- Estimate the epipoles.
- Solve linearly for the remaining entries of \( A \) and \( B \).
- 27 equations in 18 unknowns.

Exact formulae are possible, but not required for practical computation.
Matrix formulas involving trifocal tensor

Given the trifocal tensor written in matrix notation as $[T_1, T_2, T_3]$.

(i) **Retrieve the epipoles** $e_{21}, e_{31}$

Let $u_i$ and $v_i$ be the left and right null vectors respectively of $T_i$, i.e. $T_i^T u_i = 0$, $T_i v_i = 0$. Then the epipoles are obtained as the null-vectors to the following $3 \times 3$ matrices

$$
[u_1, u_2, u_3] e_{21} = 0 \quad [v_1, v_2, v_3] e_{31} = 0
$$

(ii) **Retrieve the fundamental matrices** $F_{12}, F_{13}$

$$
F_{12} = [e_{21}] \times [T_1, T_2, T_3] e_{31} \quad F_{13} = [e_{31}] \times [T_1^T, T_2^T, T_3^T] e_{21}
$$

(iii) **Retrieve the camera matrices** $P', P''$ (with $P = [I \mid 0]$)

Normalize the epipoles to unit norm. Then

$$
P' = [(I - e_{21} e_{21}^T)[T_1, T_2, T_3] e_{31} \mid e_{21}] \quad P'' = [-[T_1^T, T_2^T, T_3^T] e_{21} \mid e_{31}]
$$

Computation of the trifocal tensor
Linear equations for the trifocal tensor

Given a 3-point correspondence

\[ x \leftrightarrow x' \leftrightarrow x'' \]

The trifocal tensor relationship is

\[ x^i x'^j x''^k \epsilon_{jqu} \epsilon_{kqv} T^{qr}_i = 0_{uv} \]

- Relationship is linear in the entries of \( T \).
- each correspondence gives 9 equations, 4 linearly independent.
- \( T \) has 27 entries – defined up to scale.
- 7 point correspondences give 28 equations.
- Linear or least-squares solution for the entries of \( T \).
Summary of relations

Other point or line correspondences also yield constraints on $T$.

Trilinear Relations
Given 26 equations we can solve for the 27 entries of $T$.

- Need 7 point correspondences
- or 13 line correspondences
- or some mixture.

Total set of equations has the form

$$Et = 0$$

- With 26 equations find an exact solution.
- With more equations, least-squares solution.
Solving the equations ...

- **Solution:**
  - Take the SVD: \( E = UDV^\top \).
  - Solution is the last column of \( V \) corresponding to smallest singular value).
  - Minimizes \( \|Et\| \) subject to \( \|t\| = 1 \).

- **Normalization of data is essential.**
Constraints

- $T$ has 27 entries, defined only up to scale.
- Geometry only has 18 degrees of freedom.
  - 3 camera matrices account for $3 \times 11 = 33$ dof.
  - Invariant under 3D projective transformation (15 dof).
  - Total of 18 dof.
- $T$ must satisfy several constraints to be a geometrically valid trifocal tensor.
- To get good results, one must take account of these constraints (cf Fundamental matrix case).
What are the constraints

Some of the constraints are easy to find.

(i) Each $T^{j^k}$ must have rank 2.
(ii) Their null spaces must lie in a plane.
(iii) This gives 4 constraints in all.
(iv) 4 other constraints are not so easily formulated.
Constraints through parametrization.

- Define $T$ in terms of a set of parameters.
- Only valid $T$s may be generated from parameters.

Recall formula for $T$:

$$T_{i}^{jk} = a_{i}^{j}b_{4}^{k} - a_{4}^{j}b_{i}^{k}$$

- Only valid trifocal tensors are generated by this formula.
- Parameters are the entries $a_{i}^{j}$ and $b_{i}^{k}$.
- Over-parametrized : 24 parameters in all.
Algebraic Estimation of $T$

Similar to the algebraic method of estimation of $F$.

Minimize the algebraic error $||Et||$ subject to

(i) $||t|| = 1$

(ii) $t$ is the vector of entries of $T$.

(iii) $T$ is of the form $T_{i}^{jk} = a_{i}^{j} b_{k}^{k} - a_{4}^{j} b_{i}^{k}$.

Difficulty is this constraint is a quadratic constraint in terms of the parameters.
Minimization knowing the epipoles

Camera matrices $[I \mid 0], [A\mid a_4]$ and $[B\mid b_4]$.

$$T_{i}^{jk} = a_{i}^{j}b_{4}^{k} - a_{4}^{j}b_{i}^{k}$$

As with fundamental matrix, $a_4$ and $b_4$ are the epipoles of the first image.

If $a_4$ and $b_4$ are known, then $T$ is linear in terms of the other parameters. We may write

$$t = Gp$$

- $p$ is the matrix of 18 remaining entries of camera matrices $A$ and $B$.
- $t$ is the 27-vector of entries of $T$.
- $G$ is a $27 \times 18$ matrix.
Minimization problem

Minimize $||Et||$ subject to $||t|| = 1$.

becomes

Minimize $||EGp||$ subject to $||Gp|| = 1$.

- Exactly the same problem as with the fundamental matrix.
- Linear solution using the SVD.
Algebraic estimation of $T$

Complete algebraic estimation algorithm is

(i) Find a solution for $T$ using the normalized linear (7-point) method

(ii) Estimated $T$ will not satisfy constraints.

(iii) Compute the two epipoles $a_4$ and $b_4$.

(a) Find the left (respectively right) null spaces of each $T^{jk}$.

(b) Epipole is the common perpendicular to the null spaces.

(iv) Reestimate $T$ by algebraic method assuming values for the epipoles.
Iterative Algebraic Method

Find the trifocal tensor $T$ that minimizes $||Et||$ subject to $||t|| = 1$ and $T^{j^k}_i = a^j_i b^k_i - a^j_4 b^k_i$.

- **Concept**: Vary epipoles $a_4$ and $b_4$ to minimize the algebraic error $||Et'|| = ||EGp||$.
- **Remark**: Each choice of epipoles $a_4$ and $b_4$ defines a minimum error vector $EGp$ as above.
- Use Levenberg-Marquardt method to minimize this error.
- Simple $6 \times 27$ minimization problem.
  - 6 inputs – the entries of the two epipoles
  - 27 outputs – the algebraic error vector $Et' = EGp$.
- Each step requires estimation of $p$ using algebraic method.

Automatic Estimation of a Projective Reconstruction for a Sequence
Outline

first frame of video

(i) Projective reconstruction: 2-views, 3-views, N-views
(ii) Obtaining correspondences over N-views
Reconstruction from three views

Given: image point correspondences $x^1_i \leftrightarrow x^2_i \leftrightarrow x^3_i$, compute a projective reconstruction:

$$\{P^1, P^2, P^3, X_i\} \text{ with } x^j_i = P^j X_i$$

What is new?

- verify correspondences

- 3-view tensor: the trifocal tensor

- Compute from 6 image point correspondences.

- Automatic algorithm similar to $F$. [Torr & Zisserman]
Automatic Estimation of the trifocal tensor and correspondences

(i) Pairwise matches: Compute point matches between view pairs using robust $F$ estimation.

(ii) Putative correspondences: over three views from two view matches.

(iii) RANSAC robust estimation:
Repeat
   (a) Select random sample of 6 correspondences
   (b) Compute $T$ (1 or 3 solutions)
   (c) Measure support (number of inliers)
Choose the $T$ with the largest number of inliers.

(iv) MLE: re-estimate $T$ from inlier correspondences.

(v) Guided matching: generate additional matches.
(i) Compute all 2-view reconstructions for consecutive frames.

(ii) Compute all 3-view reconstructions for consecutive frames.

(iii) Extend to sequence by hierarchical merging:

(iv) Bundle-adjustment: minimize reprojection error

\[
\min_{P_j X_i} \sum_{i \in \text{points}} \sum_{j \in \text{frames}} d\left( x_i^j, P_j X_i \right)^2
\]

(v) Automatic algorithm [Fitzgibbon & Zisserman]
Cameras and Scene Geometry for an Image Sequence

Given video

first frame of video

- Point correspondence (tracking).
- Projective Reconstruction.
Interest points computed for each frame

- About 500 points per frame
Point tracking: Correlation matching

first frame of video

- 10-50% wrong matches
Point tracking: Epipolar-geometry guided matching

first frame of video

- Compute $F$ so that matches consistent with epipolar geometry.
- Many fewer false matches, but still a loose constraint.
Point tracking: Trifocal tensor guided matching

- Compute trifocal tensor so that matches consistent with 3-views.
- Tighter constraint, so even fewer false matches.
- Three views is the last significant improvement.
Reconstruction from Point Tracks

Compute 3D points and cameras from point tracks

- Hierarchical merging of sub-sequences.
- Bundle adjustment.
Compute VRML piecewise planar model
Example II: Extended Sequence

140 frames of a 340 frame sequence

a frame of the video
Metric Reconstruction

140 frames of a 340 frame sequence

a frame of the video
Application II: Augmented Reality

Using computed cameras and scene geometry, insert virtual objects into the sequence.

a frame of the video

330 frames
3D Insertion

a frame of the video
