2nd test series  
Discussion  
Conclusions

# Motivation

- Almost all of the standard benchmarks are solvable by simple polynomial-time problem-specific algorithms.
  - Narrow class, not representative (in general; applications)!
  - Say little about performance of planners in general!
- How were difficult instances obtained: increase the number of packages, airplanes, ... ( $\geq 2000$  state variables,  $\geq 40000$  operators, )
- Actually, 20 state variables and 40 operators is a challenge to many planners!!!

Motivation

Phase transition

Formalization

Experiments

Approaches

1st test series

2nd test series

Discussion

Conclusions

# How to get challenging benchmarks?

## Analogy: SAT benchmarks

- 1 Notoriously difficult to come by just by inventing some.
- 2 Prove that for any algorithm the problem is difficult (pigeon-hole formulas for DPLL/resolution!): not very interesting...
- 3 Go to Intel and ask for problems that resist solution. (Which company is the Intel of planning?)
- 4 Experiment with the set of **all** instances, identifying problem parameters that make planning difficult.

- 2nd test series
- Discussion
- Conclusions

# Problem instances

Characterized by the following parameters.

- 1 number  $n$  of state variables (size of state space)
- 2 number of operators
- 3 number of effect literals in operators (*our experiments: 2*)
- 4 number of precondition literals (*our experiments: 3*)
- 5 number of goal literals (*our experiments:  $n$* )
- 6 number of goal literals with value differing from the initial value (*our experiments:  $n$* ).

Motivation

Phase transition

Formalization

Experiments

Approaches

1st test series

2nd test series

Discussion

Conclusions

# Further restrictions

- Model B (Bylander 1996): no restrictions.
- Model C: each literal occurs as effect at least once.  
*Otherwise very likely some goal literals cannot be made true: many trivially insoluble instances.*
- **Model A: each literal occurs as effect about the same number of times.**  
*Model C does not fully fix the problem in Model B, so we go a bit further in Model A.*

Motivation

Phase transition

Formalization

Experiments

Approaches

1st test series

2nd test series

Discussion

Conclusions

# Experimental set-up

- Fix other parameters, and vary the number of operators.  
⇒ What happens to **difficulty** when the number of arcs ( $\sim$  operators) in the transition graph is varied?
- Number of instances for given parameter values is astronomic, so we **sample the space of all problem instances**.
- Evaluate runtimes and plan lengths of different planners.

Motivation

Phase transition

Formalization

Experiments

Approaches

1st test series

2nd test series

Discussion

Conclusions

# Approach: satisfiability planning

- First developed by Kautz and Selman (1992, 1996)
- Translate planning into formulae, find plans with a SAT solver.
- The commercially most successful planning technology (*outside planning!!!*): **bounded model-checking** since 1999 a leading technology for model-checking, mega-USD business
- Has not been considered competitive on current benchmarks. Main reason: “faster” planners give no quality guarantees.

Motivation

Phase transition

Formalization

Experiments

Approaches

SAT Planning

State-space search

LPG

1st test series

2nd test series

Discussion

Conclusions

# Planner: SP

- Our own (here: SP, for Satisfiability Planning)
- Improved problem encodings: formula size often  $\leq \frac{1}{5}$  of BLACKBOX and runtimes  $\frac{1}{10}$ ,  $\frac{1}{100}$ ,  $\frac{1}{1000}$  on big problems.
- With novel evaluation strategies very good on standard benchmarks without any benchmark-specific tricks!! See ECAI'04 paper.
- BLACKBOX about as good as SP on the small problem instances we discuss in this talk.

Motivation

Phase transition

Formalization

Approaches

SAT Planning

State-space search

LPG

1st test series

2nd test series

Discussion

Conclusions

# Approach: heuristic state-space search

- Heuristic search in the state space + distance heuristics
- Reference: Bonet and Geffner (2001)
- Favored by the planning competition community.

2nd test series

Discussion

Conclusions

# Planners: HSP an FF

- 1 HSP (Bonet and Geffner, 2001)
- 2 FF (Hoffmann and Nebel, 2001)
  - additional techniques inspired by the standard benchmarks
  - very good on standard benchmarks

Motivation

Phase transition

Formalization

Experiments

Approaches

SAT Planning

State-space search

LPG

1st test series

2nd test series

Discussion

Conclusions

# LPG: planning graphs + heuristic search

- Developed by Gerevini and Serina (1999-)
- Basic data structure: planning graph from Graphplan (Blum & Furst, 1995)
- Local search with incomplete plans ( $\sim$  planning graphs)
- Advantage over earlier planning graph approaches: length increased dynamically during search (optimality given up!)

Approaches

SAT Planning

State-space search

LPG

1st test series

2nd test series

Discussion

Conclusions

# First test series

- Model A (Results on Model C are similar.)
- 20 state variables, from 36 to 120 operators at interval  $\sim 6$
- About 500 soluble instance for each operators / variable ratio (about 8000 soluble instances out of 100000, identified by a BDD-based breadth-first search planner)
- Measure runtimes and plan lengths (timeout 10 minutes)

2nd test series

Discussion

Conclusions

# Further tests: scalability

- 20, 40 and 60 state variables ( $\sim 10^6, 10^{12}, 10^{18}$  states)
- No efficient insolubility test: could not distinguish between insoluble and very difficult instances.
- Main results for SP only (SP scales up by far the best.)
- LPG, HSP and FF: proportion of solved instances wrt SP (timeout 10 minutes)

- Plan lengths
- LPG, HSP, FF
- Discussion
- Conclusions

# Why does SP scale up best?

- 1 Like LPG, SP's problem representation explicitly uses state variables. (a fundamental difference to HSP and FF).
- 2 Powerful general-purpose inferences: unit resolution, clause learning, ..., as implemented by SAT solvers. (a main difference to LPG)
- 3 Systematic search algorithm (a main difference to LPG)

Motivation

Phase transition

Formalization

Experiments

Approaches

1st test series

2nd test series

Discussion

Conclusions

# Why does LPG scale up better than HSP, FF?

- 1 LPG's problem representation explicitly uses state variables.
- 2 State-space search in HSP and FF ignores the structural information in the state variables (and operators).
- 3 HSP and FF look at the the state variables only when computing the distance estimates.

Motivation

Phase transition

Formalization

Experiments

Approaches

1st test series

2nd test series

Discussion

Conclusions

# Why does HSP scale up better than FF?

- FF has “Helpful Actions Pruning”: ignore operators considered “not helpful” (as suggested by computation of heuristic).
- HAP is a factor in FF’s good performance on many of the big-and-easy benchmarks.
- **On easy problems performance improves and equals to HSP when HAP is disabled.**
- So HAP is a big drawback when distance heuristics do not work well (all difficult problems and many easy ones.)

Phase transition

Formalization

Experiments

Approaches

1st test series

2nd test series

Discussion

Conclusions

# Discussion

- *Are problems in the phase transition region difficult?*

Yes, for all of the four planners.

- *And outside it they are easy?*

Yes, for most of the planners. (exception: FF)

- *Do the results agree with what is known about the algorithms?*

- 1 Yes! Bounded model checking (~ satisfiability planning) good in challenging real-world problems: scalability not a direct function of the cardinality of the state space.
- 2 Yes! State-space search has not been considered a feasible approach to solve difficult problems with big state spaces (> 10 million states).
- 3 Yes/No! Standard planning benchmarks have huge state spaces and are efficiently solved by some state-space planners. **But**, these benchmarks are actually rather easy.

Discussion

Conclusions

# Relative strengths of different approaches

## STRENGTHS

- blind state-space search
- heuristic state-space search
- SAT/CSP

- Motivation
- Phase transition
- Formalization
- Experiments
- Approaches
- 1st test series
- 2nd test series
- Discussion
- Conclusions

# Conclusions

- We have proposed variants of Bylander's model of problem instances in classical planning.
- We have tested some of the main approaches to planning on instances inside and outside the phase transition region.
- Results clarify what the strengths of different approaches are.  
⇒ Interesting complement to standard benchmarks.
