## Abstract

We present a tractable analytical framework for the exact calculation of probability of node isolation when $N$ sensor nodes are independently and uniformly distributed inside a finite square region The proposed framework can accurately account for the boundary effects by partitioning the square into subregions, based on the transmission range and the node location. We show that for each subregion, the probability that a random node falls inside a disk centered at an arbitrary node located in that subregion can be expressed analytically in closed-form. Using the results for the different subregions, we obtain the exact probability of node isolation. The proposed framework is validated by comparison with simulation results.

## System Model

Consider $N$ nodes which are uniformly and independently distributed inside a square region $\mathcal{R} \in$ $\mathbb{R}^{2}$. Each sensor node has a fixed transmission range $r_{0}$. An arbitrary node will be isolated if there is no node located inside a disk $\mathcal{D}\left(\boldsymbol{u} ; \boldsymbol{r}_{\mathrm{o}}\right)$ of radius $r_{0}$ centered at that node. Let the cumulative density function (CDF) $F\left(\boldsymbol{u} ; r_{\mathrm{o}}\right)$ denote the probability that a random node falls inside the disk $\mathcal{D}\left(\boldsymbol{u} ; r_{\mathrm{o}}\right)$. It can be expressed as

$$
\begin{equation*}
F\left(\boldsymbol{u} ; r_{\mathrm{o}}\right)=\frac{\left|\mathcal{D}\left(\boldsymbol{u} ; r_{\mathrm{o}}\right) \cap \mathcal{R}\right|}{|\mathcal{R}|} . \tag{1}
\end{equation*}
$$

The conditional probability of node isolation (conditioned on knowing the location of the arbitrary node) can be expressed as

$$
\begin{equation*}
P_{\text {iso }}\left(\boldsymbol{u} ; r_{\mathrm{o}}\right)=\left(1-F\left(\boldsymbol{u} ; r_{\mathrm{o}}\right)\right)^{N-1} . \tag{2}
\end{equation*}
$$

By averaging over all possible locations of the arbitrary node, the probability of node isolation is

$$
\begin{equation*}
P_{\mathrm{iso}}\left(r_{\mathrm{o}}\right)=\int_{\mathcal{R}} P_{\mathrm{iso}}\left(\boldsymbol{u} ; r_{\mathrm{o}}\right) f_{\mathrm{U}}(\boldsymbol{u}) d s(\boldsymbol{u}) . \tag{3}
\end{equation*}
$$

The probability of no isolated node provides an upper bound for the probability of overall network connectivity as
$P_{\text {con }}\left(r_{\mathrm{o}}\right) \leq P_{\mathrm{no} \text {-iso }}\left(r_{\mathrm{o}}\right)=\left(1-P_{\mathrm{iso}}\left(r_{\mathrm{o}}\right)\right)^{N}$
(4)

## Problem Formulation

The basic building blocks in our approach to characterise the boundary effects are (i) the circular segment areas formed outside each side (border effects) and (ii) the corner overlap areas between two circular segments formed at each vertex (corner effects).

Figure 1: Illustration of border and corner effects

- $B_{1}\left(\boldsymbol{u} ; r_{\mathrm{o}}\right)$ is the area of the circular segment formed outside the side $S_{1}$, given by

$$
\begin{equation*}
B_{1}\left(\boldsymbol{u} ; r_{\mathrm{o}}\right)=r_{\mathrm{o}}^{2} \arccos \left(\frac{x}{r_{\mathrm{o}}}\right)-x \sqrt{r_{\mathrm{o}}^{2}-x^{2}} . \tag{5}
\end{equation*}
$$

- $C_{1}\left(\boldsymbol{u} ; r_{\mathrm{o}}\right)$ denotes the area of the corner overlap region between two circular segments at vertex $V_{1}$, given by

$$
\begin{array}{r}
C_{1}\left(\boldsymbol{u} ; r_{\mathrm{o}}\right)=r_{\mathrm{o}}^{2} \arcsin \left(\frac{\operatorname{abs}\left(\sqrt{\theta_{1}}\right)}{2 r_{\mathrm{o}}}\right) \\
-\frac{1}{2}\left(\sqrt{r_{\mathrm{o}}^{2}-y^{2}}-x\right) y-\frac{1}{2}\left(\sqrt{r_{\mathrm{o}}^{2}-x^{2}}-y\right) x
\end{array}
$$

where $\theta_{1}=2 r_{\mathrm{o}}^{2}-2 x \sqrt{r_{\mathrm{o}}^{2}-y^{2}}-2 y \sqrt{r_{\mathrm{o}}^{2}-x^{2}}$

- Similarly, the areas of the circular segments formed outside the sides $S_{2}, S_{3}, S_{4}$ and the areas of the corner overlap region formed at vertex $V_{2}$, $V_{3}$ and $V_{4}$ can be calculated.

## Proposed Framework

Let $\mathcal{R}_{1}, \mathcal{R}_{2}, \ldots \mathcal{R}_{M}$ denotes the type of subregions and $n_{i}, i \in\{1,2 \ldots, M\}$ denotes the number of subregion of type $\mathcal{R}_{i}$. (3) can be written as

$$
P_{\text {iso }}\left(r_{\mathrm{o}}\right)=\sum_{i=1}^{M} n_{i} \int_{\mathcal{R}_{i}}\left(1-F_{i}\left(\boldsymbol{u} ; r_{\mathrm{o}}\right)\right)^{N-1} d s(\boldsymbol{u})
$$

where $F_{i}\left(\boldsymbol{u} ; r_{\mathrm{o}}\right)$ denotes the probability that a random node falls inside the $\operatorname{disk} \mathcal{D}\left(\boldsymbol{u} ; r_{\mathrm{o}}\right)$ of radius $r_{\mathrm{o}}$ centered at $\boldsymbol{u} \in \mathcal{R}_{i} . \mathcal{R}_{i}$ and $F_{i}\left(\boldsymbol{u} ; r_{\mathrm{o}}\right)$ are defined in Table 1 and Figure 2 for different $r_{0}$.

| Proposed Framework (Continued) |
| :--- | :---: | :---: |
| Subregion $\mathcal{R}_{i}$ $n_{i}$ $F_{i}\left(\boldsymbol{u} ; r_{\mathrm{o}}\right)$ <br> $\mathcal{R}_{1}=\left\{x \in\left(r_{\mathrm{o}}, 1-r_{\mathrm{o}}\right)\right.$, <br> $\left.y \in\left(r_{\mathrm{o}}, 1-r_{\mathrm{o}}\right)\right\}$ 1 $\pi r_{\mathrm{o}}^{2}$ <br> $\mathcal{R}_{2}=\left\{x \in\left(0, r_{\mathrm{o}}\right)\right.$, <br> $\left.y \in\left(r_{\mathrm{o}}, 1-r_{\mathrm{o}}\right)\right\}$ 4 $\pi r_{\mathrm{o}}^{2}-\left(B_{1}\right)$ <br> $\mathcal{R}_{3}=\left\{x \in\left(0, r_{\mathrm{o}}\right)\right.$, <br> $\left.y \in\left(\sqrt{r_{\mathrm{o}}^{2}-x^{2}}, 1\right)\right\}$ 4 $\pi r_{\mathrm{o}}^{2}-\left(B_{1}+B_{2}\right)$ <br> $\mathcal{R}_{4}=\left\{x \in\left(0, r_{\mathrm{o}}\right)\right.$, <br> $\left.y \in\left(0, \sqrt{r_{\mathrm{o}}^{2}-x^{2}}\right)\right\}$ 4 $\pi r_{\mathrm{o}}^{2}-$ <br> $\left(B_{1}+B_{2}-C_{1}\right)$ |

Table 1: Subregions and conditional probabilities for calculation of $P_{\text {iso }}\left(r_{\mathrm{o}}\right)\left(0<r_{\mathrm{o}} \leq \frac{1}{2}\right)$.

Figure 2: Subregions for the transmission range (a) $0.5 \leq$ $r_{\mathrm{o}} \leq(2-\sqrt{2})$, (b) $(2-\sqrt{2}) \leq r_{\mathrm{o}} \leq 0.625$, (c) $0.625 \leq$ $r_{\mathrm{o}} \leq \sqrt{2} / 2$, (d) $\sqrt{2} / 2 \leq r_{\mathrm{o}} \leq 1$, (e) $1 \leq r_{\mathrm{o}} \leq \sqrt{5} / 2$ and (f)
$\sqrt{5} / 2 \leq r_{\mathrm{o}} \leq \sqrt{2}$.

Results

Figure 3: $P_{\text {iso }}\left(\boldsymbol{u} ; r_{\mathrm{o}}\right)$ versus position of arbitrary node with $r_{\mathrm{o}}=0.4, N=10$.

Figure 4: $P_{\text {iso }}\left(r_{\mathrm{o}}\right)$ versus $r_{\mathrm{o}}$.

Figure 5: $P_{\text {con }}\left(r_{\mathrm{o}}\right)$ versus $r_{\mathrm{o}}$.

## Conclusions

We have presented a tractable analytical framework for the calculation of probability of node isolation in finite wireless sensor networks. The proposed framework can accurately account for the boundary effects. - S. Durrani, Z. Khalid, and J. Guo, "A Tractable Framework for Exact Probability of Node Isolation in Finite Wireless Sensor Networks," submitted to IEEE Transactions on Vehicular Technology, 2012. [Online].
